INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

TRADE GOSSIP

Canada Iron Foundries Extend.—The contract for the erection of a $75,000 one-storey brick building for the Canada Iron Foundries, St. Maurice street, Three Rivers, P.Q., has been awarded to Nobert, Dugre, and Arsenault.

Projected Oil Refining Plants.—Alternative plans are being considered by importers of oil from the Orient, of establishing plants for the refining of oil. One plan is to refine only, while the other would include rendering.

Electric Sawmill at Nelson, B.C.—A sawmill, with a capacity of 30,000 feet per day, entirely driven by electricity, is nearly completed. It was expected to be ready for operation this week. Granite Siding will be the point of shipment.

New Post Office for London.—Semi-official news from Ottawa states that a start is likely to be made shortly in the erection of the central post office. A site was procured just before the war broke out, and it is now expected that the building will be proceeded with speedily, and the present congestion relieved.

Box Factory for Prince Rupert.—The announcement comes from Mr. F. L. Buckley, manager of the Buckley Bay and Khyex Mills, that he has just completed arrangements to lease the G.T.P. ship shed at the dry dock. It is proposed to start a box factory, cooperage, and general woodworking plant as soon as arrangements can be completed.

To Handle Extra Traffic.—With the completion of the $20,000,000 plant of the Canadian Steel Corporation that is being built at Ojibway, the Canadian Pacific Railway are looking for property for the extension of their tracks and freight sheds. New docks are in course of construction at Ojibway, and in the spring several hundred workmen's homes will be built.

The Trussed Concrete Steel Co. of Canada Limited, with head office and works at Walkerville, Ont., represented in Quebec by G. B. Reynolds, of Montreal, has received the contract for all steel sash work on the government buildings at Ottawa. This metal sash throughout will be copper coated by the Schoop process, the contract for this work being done by the Metals Coating Co. of Canada.

Large Building Operations.—It is rumored that Toronto is to be the scene of intense activity in the building line. The amount of money involved is said to be $30,000,000. The Ontario Wrecking Co. has taken out a permit to demolish nine dwellings, a church, and stable in the vicinity of Buchanan and Hayter streets, and on this site it is reported a department store will be erected to cost $10,000,000.

Wants 10,000 Men.—It is estimated that 10,000 men can be absorbed in the lumber camps east of Fort William. The Lumbermen's Association have told the Dominion government that the men must be all forthcoming within two weeks if they are to be of use for this purpose. They have sent a circular to their members asking them to get into touch with the nearest munition plants. Current wages for lumbering are to be paid, arrangements having been made with the Minister of Labor to this effect.

To Interest British Capital.—Efforts are being made here to induce British capitalists to purchase the war munitions plants in Canada and create new peace industries. The contracts now being filled will be gradually reduced so as not to cause congestion in the labor market. Sir Joseph Flavelle will have full charge of the demobilization of the munitions industry in Canada under the Imperial Munitions Board. The total British war orders placed in Canada amount to $1,-300 000 000.—"Montreal Gazette."

Supplies Burned.—Early in the month damage to the extent of about $100,000 was caused by a fire originating from defective wiring, to one of the large storage buildings situated on the King's wharf at Quebec. A large quantity of supplies for the lower St. Lawrence lighthouses, and medicine for la grippe sufferers of the district, stored in the basement, was saved, but large supplies on the top floor were totally destroyed. The value of the stores was approximately $75,000, the remainder being on the building. The store house was of stone, built in 1820.

Paper Mills Can Take Men.—The Canadian Pulp and Paper Association has received a request from Hon. D. G. Robertson, Minister of Labor, for information as to the number of additional men the industry can employ this winter. Normally the industry employs about 25,000 mill and office employees, and at certain times in the year, about as many woodsmen. It has contributed 2,500 men to military service, most of whom have been assured of their positions on their return. As this will take some time, they can employ several thousand men immediately.

Operating as Usual.—Darling Bros., Montreal, expect to complete their contract on the 4.7 anti-aircraft shell for the American government. No instructions have been received to the contrary and employees have been notified that the plant will operate as usual until further notice. If their present order is to be completed the plant will operate throughout the winter. The night shift will be continued unless advice is receiv-

CANADA'S FUTURE RESTS LARGELY IN HER OWN HANDS

We Hold the Cards, But They Must Be Properly Played —The Testing Time is at Hand Now

By C. GRAHAM DRINKWATER, Vice-Pres. Canadian Fairbanks-Morse Co., Ltd.

You ask what is in store for us as a nation, and my humble answer must be: "Just exactly what we have the ability to make it. We hold the cards but they must be properly played. The test is at hand. We rose to the occasion on the outbreak of war. Our army overseas has made a glorious record, and our army of workers at home has set a new standard in the production of war materials. Canada's prestige never stood higher, and if we apply the same breadth of vision to the period of reconstruction, our success will be assured."

ed to the contrary. Their domestic activities are quite extensive at the present time, and should shell work cease, it is probable that quite a number of men could be absorbed in the general work.

St. Thomas Goes After Industries.—St. Thomas is sending its commissioner, Mr. McMahon, to New Jersey, where several likely opportunities to secure new industries for the town exist. He was authorized to offer special inducements to certain industries there to locate in St. Thomas. There will be several factories available when the existing munition works close down, which will be very shortly. One of the industries that will probably be offered inducements is a large silo and granary manufacturing concern. The Board of Trade and Industrial Committee will probably hold a membership campaign this winter.

This Plant to Work All Winter.—"All men and women employed in Winnipeg shell factories as metal trades workers will be needed during the coming winter." This statement was made by L. B. Barrit, general manager of the Vulcan Iron Works. The Vulcan Iron Works, Manitoba Bridge and Iron Works, and Dominion Bridge and Iron Works, who have a contract for $500,000 placed with them by the American government, employ 500 men extra to fill the contract. T. R. Deacon, manager of the Manitoba Bridge and Iron Works, thinks that there will be no change in the number of people employed by the metal trades, due to the end of the war.

Discarding List Welcomed.—Canadian manufacturers, who have been inconvenienced by the Preference Act in the U. S. A., expressed great pleasure when it was discontinued. The Canadian Manufacturers' Association, commenting on the announcement from Washington, said that it meant the cutting of a vast amount of red tape which was necessary in war time, but not in peace. The officials of the Canadian Manufacturers' Association do not look for any hard times in Canada during the reconstruction period. As they say, a country that could do what Canada has in the war is capable of taking care of the present situation and bringing things back to normal very soon.

Notice of Removal.—The Canadian Bond Hanger and Coupling Co., formerly of Alexandria, Ont., have sent out the following notice to the trade: "Under date of July 6th we advised you of our pending removal to our new plant at Toronto. Continued orders from the trade made this move impracticable at that time without causing you considerable inconvenience with respect to deliveries. We are now transferring our stock and equipment from Alexandria, and our office will be established at the new location on November 20th, after which date will you kindly address all communications for us to Villiers and Munitions Streets, Toronto, and greatly oblige. Toronto telephone: Adelaide 166."

Selling Peace Lines.—According to reports coming from heads of departments of firms dealing in machinery and transmission, there have already been a number of inquiries for the fitting out of plants that will turn out work separate and apart from the war industries. "I have sold motors," stated one dealer, "to a firm that has a contract for the building of fifty houses in one of the best industrial centres of Ontario. There are inquiries coming in from similar firms elsewhere. The flax industry seems to be in for a period of development, and although we do not handle the special machinery for this work we are interested in the transmission end of the business, and it is for this that the inquiries are coming."

Letting Staffs Out.—From a survey of the situation in Toronto, it would seem that about twenty per cent. of the munitions workers had been let out so far. The figures may go as far as 25 per cent., but not over. In other places where production is still going on, Sunday work has been dispensed with. There is a disposition on the part of many of the plants to try and hold the better mechanics whether they have immediate use for them or not. In a good many instances it is found that the foreigner is being let out ahead of the English-speaking worker. It is anticipated that the process of discharging the employees of the munitions plants will proceed more rapidly in the next week or so. It is estimated that Toronto has had about 26,000 munitions workers, and that at present between 6,000 and 7,000 have been let out.

Montreal Cancellation.—The St. Lawrence Machinery Co. received instructions from the Imperial Munitions Board to cease operations on the 6-inch British shell last Saturday night. They had expected to complete their contract, involving about 2,000 more shells, but these will now be a factor for future adjustment. This firm has been operating two plants, one of which has been leased for the specific purpose of munitions making. The original plant of the St. Lawrence Iron Foundry, which has been utilized for shell production for nearly four years, will revert back to grey iron foundry work, many of the old moulders and foundry men having been engaged in the shell activity. Work in connection with the foundry will be started as soon as settlement is made regarding shells now on the premises. All of the foundry equipment is still available and operations can be resumed as soon as the flooring and machinery is removed.

Disbanding Flyers.—Within about the end of January next, the bulk of the members of the 12,000 mechanics and cadets who form the personnel of the Royal Air Force will have been disbanded and back in civil life, according to an authoritative announcement at the local headquarters of the R. A. F. Demobilization commenced actively, and when in full swing 400 men will be returned to civil life every day until the force is disbanded, except for the small office staff, which will be retained to deal with the pilots returned from overseas who must be discharged in Toronto. The R. A. F. of Canada has grown to a multi-millionaire corporation, and the property which the corps owns in Canada at the present time is stated to be between $30,000,000 and $40,000,000, much of which, as capital stock, has been written off in the training of pilots. The cost of training each pilot is thus shown on the books of the force as somewhere in the neighborhood of $12,000, and the property will be worth only its salvage value unless some means can be found to dispose of it.

PERSONAL

Corp. Gordon D. Richardson, assistant sales manager of the T. A. Willson Co., Reading, Pa., was wounded in the hip by machine gun fire during the last few hard smashes at the Hindenburg line. He is improving at U.S. Army Base Hospital, Portsmouth, England. Corp. Richardson is well known to the Canadian industrial trade.

Mr. Ed. Fitzgerald, for some time past connected with the Imperial Munitions Board at Ottawa, has received an important appointment with the Hudson Bay Co. He was, previous to joining the Imperial Munitions Board, assistant general-purchasing agent to the C. P. R., under Mr. E. N. Binder. It is understood that he will leave for the West towards the end of the year.

The steel trade will learn with sincere regret of the death of Lawrence Johnston, assistant purchasing agent for the Steel Company of Canada, Hamilton. He had been with the Steel Company for the last ten years, and was well known, not only in Hamilton, but in the whole district covered by the industry. He was taken with influenza, after which pneumonia developed. He had been sick only a week. He leaves a wife and two children.

MARINE

Vancouver, B.C.—The Northern Construction Co. are constructing an addition to their yard, to cost $44,000. This company is building 5 vessels of 1,500 tons d.w. for the French Government.

New Westminster.—Good progress is being made on the five 1,5000-ton wooden vessels for the French Government, building at the New Westminster Construction and Engineering Co. Four of them are in France, and three of these planking and ceiling are in progress.

Toronto.—The Canadian Car & Foundry Co. filled the order for the 12 mine sweepers for the French Government in such a satisfactory manner that they have secured a further order for a number of steel steamers for the same Government.

Vancouver, B.C.—A meeting of residents of the Yukon passed a resolution, calling on the Canadian Government to confer with the U.S. Government on the question of placing a lighthouse on Vanderbilt Reef, in Lynn Canal, where the "Princess Sophia" was recently lost.

Montreal. — The vice-president and managing director, Mr. J. W. Norcross, and two other directors of the Canada Steamship Lines, have left Canada for England. It is stated that the London Advisory Board has invited them to confer on the question of continuing the ocean trade of the company, which came into existence since the beginning of the war. The company has at present twenty vessels in the Atlantic trade.

Washington. — Chairman Hurley, of the Shipping Board, who sailed for Europe to prepare for the returning of American troops to this country and for moving needed food supplies to the war-famished nations overseas, also plans to seek an international agreement between the governments, shipping interests and labor organizations of the principal maritime powers for standardization of seamen's wages and working conditions. It was said that Mr. Hurley expects to propose that the American laws and the agreements between the Government and the seamen's unions on these subjects be accepted as the standards, and it is understood that the American Federation of Labor and the British Seamen's Union are prepared to support the proposal.

Port Arthur.—Launching of ocean-going tug "Victorie" took place at the plant of Port Arthur Shipbuilding Company, Limited, Port Arthur, Ontario, November 8th, Mrs. J. T. Emmerson, of Port Arthur, acting as sponsor. The "Victorie" is an all steel ocean-going tug built to Lloyd's classification, designed to develop 800 horsepower. General dimensions are as follows: Length B.P., 119 ft.; breadth, molded, 26 ft.; depth, molded, 26 ft. 6 in. Propelling machinery consists of a triple expansion surface condensing engine having three cylinders, sizes 15 in.; 29 in. 47 in. x 36 in. stroke. Steam is supplied by two Scotch boilers, diameter 11 ft., length 11 ft., each with a working pressure of 100 pounds. This tug is to be delivered before the close of navigation this year.

IN INDUSTRIAL HAMILTON

(Continued from page 636)

Company, Canadian Cartridge Company, Oliver Chilled Plow Works Company, Sawyer-Massey Company, International Harvester Company, Sanford Clothing Manufacturing Company, and others, will all avail themselves of the peculiar and timely opportunities which the Lyons fair holds out for the Canadian manufacturer who is anxious to develop foreign trade.

WE SHALL TELL YOU WHEN TO CEASE IT

And so Turning Out of the American Munitions Contracts Keeps Up

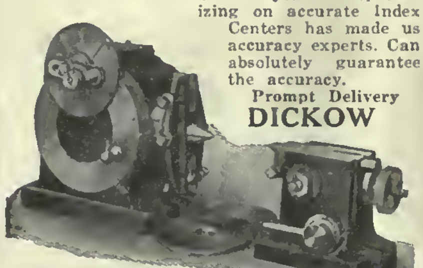
Hamilton.—Just how much longer local companies will be engaged on munition work is a question, but the fact remains that those which are working on American government orders have shown no cessation, while several of them have received intimations from Washington, it is said, that ensures their continuing on shell work for many weeks yet.

One such company is the Tallman Brass & Metal Company, which has worked almost exclusively on munition work since the outbreak of war, and which only a short time ago received large shell orders from the American government.

Addison H. Tallman, manager of the company, said that not long ago munition equipment costing $150.000 had been installed, yet he would not like to hazard how much longer the company would continue on such work.

Would Notify Them

Another manufacturer, working on American munitions, grew apprehensive when the armistice was signed, and wired Washington to find out what lay ahead of him. The reply he received from Washington was to continue on



shell work without any let-up. "We shall tell you when to cease," the message ran.

That these orders must soon be cancelled, however, was generally admitted.

Mr. Tallman said that the fixture department of his company had sufficient work on hand to keep it busy for four months. Much of this work would be for foreign markets. With the automobile industries coming into their own again, however, Mr. Tallman said that his company should have plenty of work to do in making brass attachments for autos. The activities of the shipbuilding industry would also give the company much to do, as it is in a position to make all sorts of brass fixtures for vessels, such as binnacles, signal lamps, cabin railings, clock-cases, etc. Mr. Tallman said that he had received word to slow up on shrapnel bullets for the Imperial Munitions Board. Only six men would be affected, and would be easily absorbed by other departments once the work was stopped.

Cutting Off Forging

Manufacture of all six-inch shells for the Imperial Munitions Board ceased in Hamilton last Thursday, and shell forgings ended on Saturday night. The largest maker of these was the Dominion Steel Foundry & Steel Ltd. One thousand men were laid off temporarily, but will soon be back at their places again when the present equipment is removed and tools for new work are installed.

Paul J. Myler, of the Canadian Westinghouse Company, stated that no word had been received to cease making shells for the American government. Large orders are on hand, and the company expects that this work will continue for several weeks.

STEEL CO. SENDING MAN TO AUSTRALIA

George Spence Going On An Extensive Trip to Look for New Markets

Hamilton.—Believing that there are virgin markets to be developed for their smaller bright goods in Australia, New Zealand, and other places in the Antipodes, the Steel Company of Canada has appointed George Spence, of this city, to make an extensive tour of those countries to develop markets for screws, bolts, and other bright goods.

Mr. Spence, who will depart for Australia at a no distant date, is a native of Hamilton, and has been associated with the Steel Company of Canada for many years. He received his training in the sales department of the company, and showed such promise that it was not long before he was sent to New York to take charge of the company's export office at that point.

Mr. Spence will be succeeded by Mr. James, who has been attached to the Montreal offices of the company for several years.

POWER SHORTAGE FELT IN LONDON

LONDON, Nov. 27.—Shortage of power is affecting the manufacturers of London. It was thought that when the armistice terms were signed the demand for power would not be so heavy by the munitions factories. This has not helped out the situation so far as London is concerned as the manufacturers have cut out the night shift only. During the peak lead, which is between 4.30 and 6 o'clock in the afternoon, the power is so short that domestic users are handicapped by the low voltage.

E. V. Buchanan, General Manager of the Public Utilities Commission, has issued letters to all large power users asking them to cut their power by 50 per cent. at 4.30 and shutting it off completely at 5 o'clock, in order to save the situation. He points out that the domestic consumer has been sacrificing for the sake of the manufacturers and he thinks that now that the need of munitions is not great the manufacturers can shut down on their power without much inconvenience.

About twenty users of power have responded to the request and it is thought that this will enable the city to weather the power shortage successfully.

Ready for Export

McClary Manufacturing Company is already preparing in anticipation of a large export trade with European countries that Canada will get as soon as the peace terms are definitely settled. The company has shipments waiting for the removal of the embargo to be forwarded to Africa, Russia, Australia, and New Zealand. J. J. Foot, vice-president of the company, says that he looks for a good trade with these countries.

The company is also planning an exhibit at the Fair at Lyons, in France, next year, with a view to establishing trade relations with that country. McClary Manufacturing Company manufactures a complete line of stoves, ranges, furnaces, and all kinds of enamel and granite ware.

SHELL WORKER IS ONE OPERATION MAN

Editor, Canadian Machinery: In reply to your request for my opinion of the effect shell machinists will have on the qualified machinists' trade, I state the following facts:

My candid opinion is that shell machinists will be a great detriment to skilled mechanics in this way. Unskilled help on production work with the aid of gauges, etc., will take the place of mechanics, and will do just about as accurate work. The manufacturer will take advantage of this fact and keep down and reduce rate of pay.

Regarding the matter of work in toolrooms, machine and job shops, where a varied line of work has to be undertaken and completed from start to finish, the "shell buster" will be a failure, as he is a one job man, and a one job man he will remain.

Sincerely yours,
W. Pirie.

POSITIONS WANTED

SALESMAN WITH PRACTICAL MECHANICAL and selling experience, at present employed, desires advantageous change with reliable firm. Married, age 33. Box 519, Canadian Machinery. c22m

EXPORT—EXPERIENCED SALESMAN WELL introduced with Belgian, French and Italian railroads and other important industrial firms is open for European representation. Will sail soon. Address Box 529, Canadian Machinery. (c23m)

HEAT-TREATER—SIXTEEN YEARS HARDening, tempering, carbonizing, heat-treating, with sound practical and technical experience metallurgy and pyrometry. Up-to-date methods and know how to handle men. Sound credentials. Box 526, Canadian Machinery. (c22m)

FOUNDRY FOREMAN OPEN FOR ENGAGEment, has had years of experience on best class of work. Economical production of castings, successful handling of men, mixing of metals. Can furnish best of references. Joseph Crowe, 376 Brock St., Peterborough, Ont. (ctfm)

WANTED—POSITION AS MACHINE SHOP superintendent. At present engaged in similar capacity in large plant. Desire change. 18 years' machine shop experience. Thoroughly practical. Accustomed to heavy work. Locomotive and marine credentials. Age 36. Address Box 522, Canadian Machinery. (c21m)

RETURNED SOLDIER DESIRES POSITION as mechanical draughtsman. Can do tracing and wants to learn more about machine drawing. Would be willing to start with a moderate salary if prospects are good. Am at present employed in large drafting room and would like similar position in Toronto or Montreal. Other office work would be considered. Box 520, Canadian Machinery. c22m

ASSISTANT GENERAL SUPERINTENDENT of large engineering plant seeks similar position or that of general superintendent. 22 years' machine shop practice, both locomotive and marine. Thorough mechanic. Good executive. Age 38. Disengeged November twentieth. Address Box 621, Canadian Machinery. (c20m)

SPECIAL MACHINERY

H. C. THOMAS, GENERAL MACHINE SHOP, tools, jigs and machine repairs. 301 King St. W., Toronto. Telephone Adelaide 3836. tf

MANUFACTURERS—WE CAN UNDERTAKE work to any specification—munition production equipment or otherwise. Write W. H Sumbling Machinery Co., 7 St. Mary St., Toronto

MISCELLANEOUS

Munition Manufacturers

If you have not decided what use to make of your plant, I have a good proposition that might interest you. Send address. I will call. Box 520, Canadian Machinery. (c24m)

HELP WANTED

SUPERINTENDENT WANTED AT ONCE FOR small machine shop in Toronto. Good chance for right man. Box No. 514, Canadian Machinery. c22m

GRADUATE MECHANICAL ENGINEER wanted. Only energetic and ambitious men need apply. Specialty gasoline motors and farming machinery. Knowledge of French necessary. Highest salary paid to right party. Send references and state salary desired. Apply Box 482, Canadian Machinery. (ctm)

WANTED—ASSISTANT SUPERINTENDENT of Montreal factory. Must be experienced mechanical engineer with knowledge of drafting. Give full particulars as to experience. State age and salary required. Box 527, Canadian Machinery. (c23m)

WANTED—THOROUGHLY PRACTICAL AND experienced Mechanical Engineer with executive ability for position as Chief Engineer in a large steel working plant, chiefly engaged in the production of shell and heavy Marine Forgings; knowledge of Hydraulic Presses and Pumps desirable—a good position and salary for right man. Apply Canada Forge Company, Limited, Welland, Ont.

MACHINERY WANTED

SPIKE MACHINE—WE WANT TO BUY A machine for making railway and ships' spikes. Either new or second-hand. Address, giving full particulars, Starr Manufacturing Company, Limited, Dartmouth, Nova Scotia, Canada. (c23m)

ONE SECOND-HAND GAS ENGINE ABOUT 100 h.p. Must be in good condition. Write P.O. Box 217, Moncton, N.B. (c24m)

WANTED—ONE UNIVERSAL MILLING MAchine, size No. 2 or 3. One tool room grinder, No. 2. Send full particulars to Box 528, Canadian Machinery. (c24m)

WANTED—GOOD SECOND-HAND MACHINE for straightening bars of steel from one-half to two and one-half inches. Give full particulars as to make of machine, length of service, price, etc. Box 523, Canadian Machinery. (c22m)

WANTED — SECOND-HAND AUTOMATIC screw machine, plain or turret type. Single spindle. Capacity 1⅛ or 1¼ stock. Address particulars and price to Box 530, Canadian Machinery. (c24m)

1—BELT DRIVEN AIR COMPRESSOR ABOUT 8 x 8 cylinder.
1—Lathe to take in 12 ft. between centers.
2—10-ton, hand operated travelling cranes, 38 ft. span. The National Shipbuilding Co., Ltd., Goderich, Ont. c19m

PATTERNS

TORONTO PATTERN WORKS, 65 JARVIS Street, Toronto. Patterns in wood and metal for all kinds of machinery. (cfm)

FOR SALE

RADIAL DRILL, BICKFORD, 4', SPEED BOX drive, in good condition, for sale. Boving Company, Lindsay. (c22m)

FOR SALE—ONE CENTRIFUGAL PUMP, 4-inch suction; one Pickering steam governor, inch and half; 5 wood pulleys, 24 by 6-inch; 1 do., 16 by 6-inch; 1 do., 12 by 10-inch; 500 feet wire cable, three-eighths. Apply A. G. Anderson, Port Dover, Ont. (c24m)

FOR SALE—THREE NEWTON COLD SAWS in good condition. $1,500 each for quick sale. Canada Metal Co., 35 Fraser Ave., Toronto. c25m

FROG AND SWITCH PLANERS:—SIZES 36" x 12" x 14' and 36" x 12" x 12' in good second-hand condition. Box 524, c/o Canadian Machinery. (c22m)

FOR SALE — FOUR-INCH CENTRIFUGAL pump; also horizontal boiler 8' long, 42" dia., 50 x 2½" tubes. In good shape. Box 516, Canadian Machinery. c21m

FOR SALE—300 BOXES IC AND IX 20" x 28" Prime Tinplates. These plates can be bought below present market prices. The Schultz Mfg. Co., Limited, Hamilton, Canada. (c22m)

FOR SALE—TWO No. 210 AND ONE No. 190 Brown & Boggs Punch Presses in good condition. Price $400 each f.o.b. cars. Write or call. Canada Metal Co., 35 Fraser Ave., Toronto. c25m

FOR SALE—1—7' x 100' ROTARY KILN—½" shell in good condition. Immediate shipment. Price reasonable. Location, Ontario, Canada. Address Box 525, Canadian Machinery. (c22m)

FOR SALE—TWO NILES RAIL AND FROG miller, 4-spindle drilling machines. Two Newton cold saws, No. 501 and two No. 502. Also frog and switch planers. J. L. Neilson & Co., Winnipeg, Man. (c23m)

FOR SALE—1—36" x 36" x 12' Bertram Planer, single head in first-class condition. 1—64" x 6' Horizontal Boring Miller, single back geared, in good condition. Globe Engineering Co., Ltd., Hamilton, Ont. ctfm

LATHE FOR SALE—$500, SWINGS 36" OVER saddle; bed, 16' long; double ended; practically two lathes on same bed. Turnbull Elevator Mfg. Co., Toronto. (ctm)

MACHINE SHOP IN TORONTO FOR SALE, in existence for the last fifteen years. Equipment in good condition, plenty of work on hand, making good profits. Will bear strictest and best investigation. Only principals will be considered. Box 517, Canadian Machinery. c22m

FOR SALE—RACINE POWER SAW IN GOOD condition. 12" frame. $75.00 each for quick sale. Canada Metal Co., Ltd., 35 Fraser Ave., Toronto. (c25m)

8—800 AMPERE "SHAWMUT" KNIFE BLADE fuses for 250-volt D.C. current. 2—6" Walworth gate valves, O.S. & Y., bolted bonnet, flange ends. 1—65 H.P., 60-cycle, 3-phase, 550-volt, 1,200 r.p.m. induction motor. Box 620, New Glasgow, N.S. (c24m)

TWO LOWDOWN TRUCKS FOR SALE. A. B. Ormsby Company, Limited, 48 Abell Street, Toronto. (c27m)

Principles and Practice of Mechanical Drawing

In Article Seven the Author Takes Up Conventions Relating to Gear Drawing, Assembly Drawings, Detail Drawings and Abbreviations

By TERRELL CROFT

THE drawing of gears is relatively simple as compared with the process of designing them. It is beyond the scope of this discussion to consider gear design. Hence, only the methods of showing a gear which has been designed will be treated. Many men, who are capable of correctly designing gears, are not familiar with the accepted practices in their representation. That is, they do not know which views should be shown and do not understand the correct methods of dimensioning. The practices, which are illustrated and described here, are typical of those now being followed generally by the most progressive concerns.

Spur gears can be shown by very simple drawings (Fig. 1) where the teeth are to be cut on a milling machine or gear shaper. It is not necessary to show the teeth in detail where they are to be machined by one of the methods just mentioned. The contour and spacing of the teeth are determined by the setting of the machine tool. The "pitch" required should, of course, be shown on the drawing, so that the machinist may adjust the tool accordingly. On the drawing (Fig. 1) it is necessary to show only the depth of the teeth. This may be done in the sectional view, as suggested in the picture, by sectioning up to the base of the teeth. In other words, the gear "drawing" for the smaller gears shows only the blank from which the finished gear is ultimately cut. The completed drawing should set forth the necessary dimensions, so that it will not be necessary for the machinist to do any figuring when cutting the gear. By following this practice time and money will be saved. On the drawing should be specified the number of teeth, pitch, and the pitch diameter.

Bevel gear drawings usually appear about as shown in Fig. 2, which indicates the dimensions and details commonly required. Two views—a section and a half-elevation—usually specify the part completely. Note that for a bevel gear it is necessary that the angles of the cuts be specified. As with spur gears, the number of teeth, the pitch and the pitch diameter should be indicated on the drawing.

Drawings of large spur or bevel gears, for which the teeth are molded rough, should show the outline of the teeth for the information of the pattern-maker. It is not, however, necessary or desirable that all of the teeth all the way around the circumference of the gear be drawn in detail. It is ample to plot in the exact form of only one or two teeth. The exact curves of these teeth outlines should, for the information of the pattern-maker, be shown in such a way that he can reproduce them accurately. If this is not done, the pattern-maker may employ some approximate method in plotting the teeth outlines, which will not provide the form which is really necessary.

A worm gear (Fig. 3) has curved-face teeth cut in its periphery, into which a worm engages or meshes. As with the gears of the other forms, two views—a section and a half-elevation—are, ordinarily, all that is required to furnish the essential information. The pitch diameter is given at the throat of the gear teeth. That is, it is the smallest possible pitch diameter for the gear in question.

A worm (Fig. 4) is merely a screw

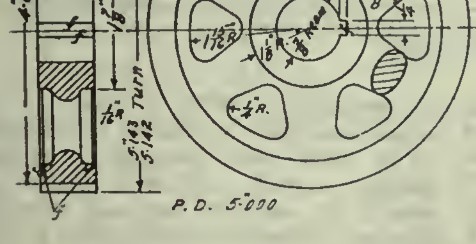

FIG. 1—TYPICAL DETAIL OF DRAWING OF A SPUR GEAR

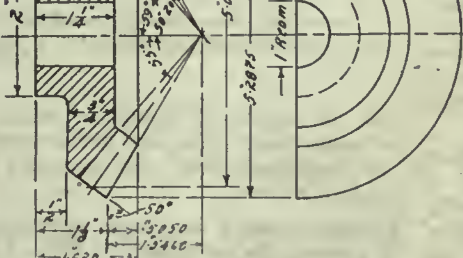

FIG. 2—METHOD OF SHOWING THE DETAILS OF A BEVEL GEAR.

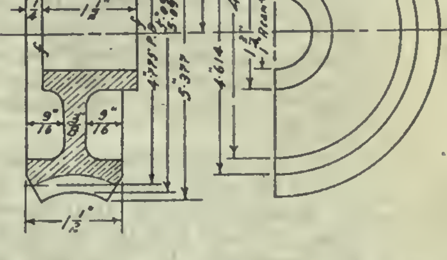

FIG. 3—DETAILS OF A WORM GEAR RENDERED IN ACCORDANCE WITH MODERN PRACTICE.

having threads which are similar to those of the Acme design. This screw has a cylindrical hole bored through it longitudinally in which the shaft which drives, or which is driven by the worm, may engage. The threads are considerably deeper than ordinary Acme threads, but the slope of the sides is the same—namely, 14½ deg. There may be one or more threads on the worm just as there may be a single, double, or triple-threaded screw. Therefore, it should be specified whether the thread required on the worm in question is to be single, double, or triple. Furthermore, it should be shown whether it is to be a right-hand or a left-hand thread. If not otherwise indicated on the drawing, it is ordinarily assumed that the thread is to be single and right-hand, "RH." The lead (Fig. 4) as well as the pitch and pitch diameter should be noted on the sheet.

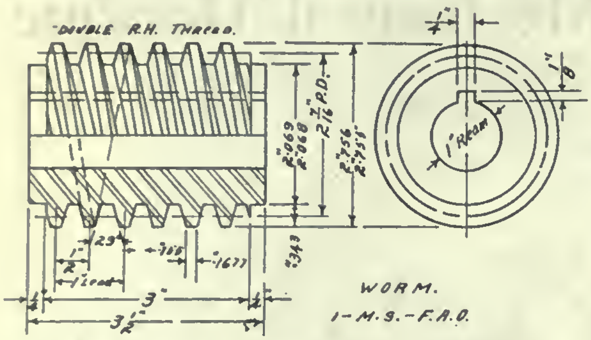

FIG. 4—WORM FOR MESHING IN WORM GEAR.

Assembly and detail drawings are necessary when any object comprising a number of parts is to be reproduced graphically for constructional purposes. Where drawings are made for construction it is, as has been emphasized hereinbefore, essential that the contours, dimensions, finishes, materials, and the like be specified in detail so that the mechanics, who are to construct the device, can proceed with minimum effort It is obvious that it would be impossible to show on one assembly drawing, of even a relatively simple device, all of the information that is necessary for its concrete reproduction. Consider, for example, the oil cup of Fig. 5, which is, comparatively speaking, an uncomplicated thing. Upon consideration it will be apparent that it would be out of the question to indicate the sizes, materials, screw threads, finishes, and the like of each of the component parts on the assembly drawing of Fig. 5. It is, therefore, usually necessary to show the completed object in an "assembly drawing." Then in addition a number of minor drawings showing each of the components separately and specifying them in detail are required. Therefore, it follows that:—

An assembly drawing is one which shows the completed object with all of its parts in place in their correct relation. It shows how the various "details" fit together. An assembly drawing, clearly made and indexed, is of great assistance in economical production.

A detail drawing is one which specifies in detail the construction of one of the component parts of a machine or mechanism, so that the necessary information and dimensions may be given on it, from which the shop man can work.

Sometimes the assembly drawing is made before the details and sometimes after. Which procedure is followed will depend wholly upon the characteristics of the device which is being designed. Frequently, particularly with large complicated machines, it is necessary to first make an assembly drawing which will show the completed contrivance as the designer conceives it. Then, from this plot, each of the component parts is detailed into an individual drawing of its own. The designer may find when he is making the detail drawings that it is desirable to modify the construction which he originated in the assembly. If such is the case the assembly sheet can be rectified accordingly. After all the details have been drawn, they are checked against the assembly, and if the detail drawings and the assembly drawing reconcile with one another, the tracings are then made. On the other hand, it is sometimes more convenient, particularly where the device is a simple one, to sketch in, or draw to scale, the component parts and then combine them into the assembly sheet. Sometimes the preliminary layout is merely a sketch or series of sketches from which the detail drawings are developed and the assembly ultimately made.

The assembly and detail drawings for a grease cup are shown in Figs. 5 to 8, inclusive. Fig. 5 is the assembly in which the different elements are brought together into a completed unit. While this grease cup is, as previously suggested, relatively speaking, a very simple affair, the method of showing it in assembly and in detail is in general the same as one which would be followed in showing any contrivance, no matter how large or complicated. One important principle, which is well followed and illustrated in Fig. 5, is that the assembly should be so rendered that it will show as completely as possible the actual construction and arrangement of the device under consideration. In Fig. 5 this end has been attained by showing the cup partially in section so that the piston, adjusting screw, spring, and screw valve are all exposed. The result is much more effective than if the sectional method of presentation were not adopted. On the detail sheets (Figs. 6, 7 and 8) every item of information is recorded which will be of assistance to the various mechanics—pattern-makers, molders, machinists, foundrymen, and others—in the plant in the completion of their work.

Whether one detail or several should be shown on the same detail sheet is a question the answer for which must also be determined by the conditions affecting the case. Some shops make it a practice to show only one part on a detail sheet. This policy has the advantage that a single detail on a sheet is less confusing to an inexperienced workman than where he must refer to a drawing which contains the specifications for a large number of different parts. On the other hand, the practice of detailing a number of parts on a single sheet has the element of economy in its favor. Both methods are being used successfully. Where a number of details are shown on the same sheet it is usually desirable to locate them in the

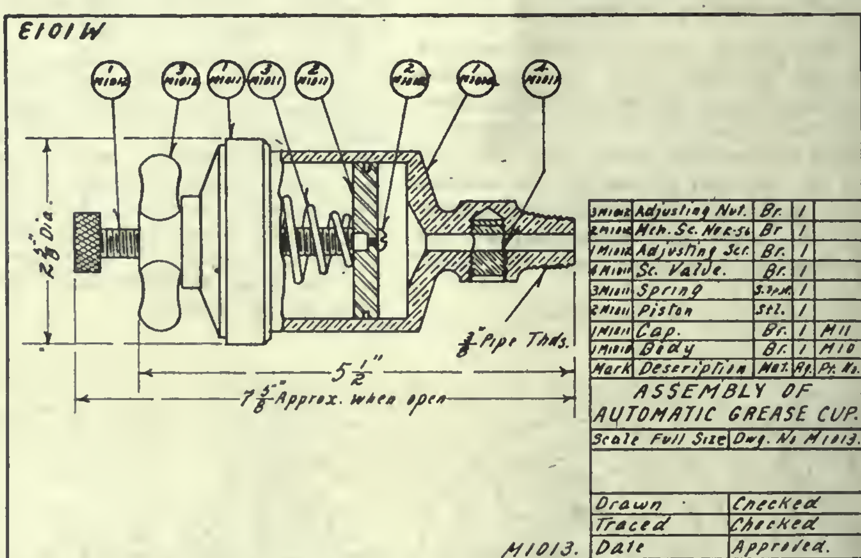

FIG. 5—ASSEMBLY DRAWING OF A GREASE CUP, ILLUSTRATING THE PRINCIPLE AND DETAIL VIEWS.

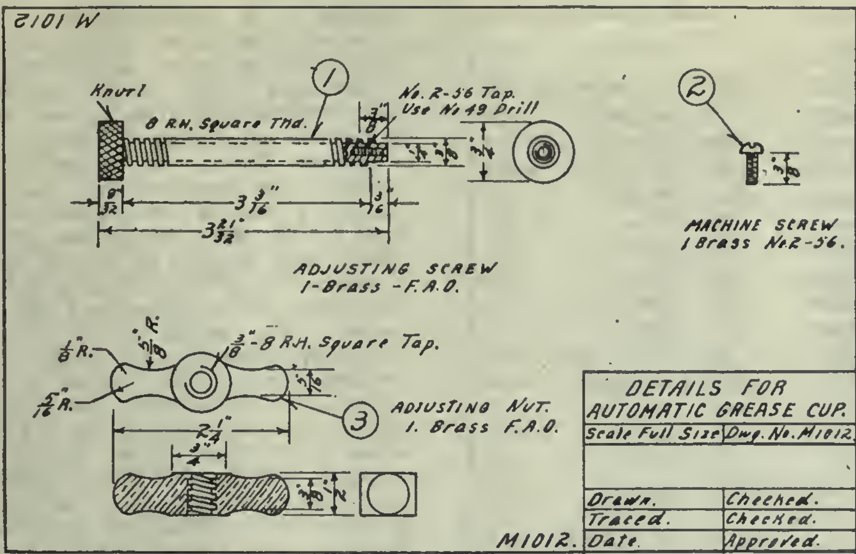

FIG. 6—ADJUSTING SCREW, ADJUSTING NUT AND MACHINE SCREW.

positions relatively to one another which they will occupy in the assembled device.

Methods of indexing the parts on an assembly drawing are many. However, that which is illustrated in Figs. 5 to 8 is adequate and satisfactory for the average condition. The indexing system consists of the index table above the drawing title on the assembly sheet (Fig. 5) and the circles in which are indicated the parts and detail drawing numbers. The index table on the assembly sheet gives the name, the part number, the material, the pattern number, and the number of each required for all of the details. To tie in with this index, each component must be assigned a number. Thus the number for each part is shown within a circle from which a leader extends to the part. Also within the circle is the sheet number, which gives the detail drawing of the part in question. The upper and smaller number in each circle is the part numober, and the lower number is the detail drawing number. Where only one detail is shown on a sheet, as for example, in Fig. 8, where the number M1010 is shown, the detail drawing number is sometimes considered as providing sufficient identification without the addition of the part number. But where several parts are detailed on the same sheet, as in Figs. 6 and 7, then it is absolutely essential that the different parts be assigned numbers, such as 1, 2, 3, etc., etc. These numbers, together with the detail sheet number, will prevent confusion. Always commence the series on each sheet with the figure "1." This insures that a part may be located regardless of name if its part number and the number of the sheet are known. The part number is always placed within a circle near the object to which it refers so it will catch the eye readily.

Abbreviations should, insofar as is feasible, be standardized. For some purposes abbreviations are necessary and desirable. On the other hand, it is a mistaken policy to use too many different ones on drawings. The reason is that where many are used the mechanics must have exceedingly elastic memories to retain them, and as a consequence, confusion and errors may result. As an example of a necessary abbreviation may be cited "F.A.O.", meaning "Finish All Over." This symbol is used so frequently that it would be a waste of time to spell it out always. All mechanics understand its meaning. Again, it is usually desirable to abbreviate the names of the different constructional materials so that the symbols representing them will occupy minimum space in the part index on the assembly sheet. Unfortunately, it appears that every drafting organization, plant, or factory has its own set of abbreviations. No generally accepted list of standard abbreviations is, insofar as we are aware, available. The result is general confusion. The drawings of one concern can not be interpreted quickly and accurately by the members of the organization of another concern, which may desire to do business with the first.

The list of abbreviations shown in Fig. 9 has been carefully selected after studying the practices of a number of progressive concerns. This list is about as long as one as should be adopted

FIG. 9—TABLE SHOWING LIST OF APPROVED ABBREVIATIONS.

for general use. There are many other abbreviations which are in use, but they are, in general, of special character. They relate usually to some particular industry or have been adopted by some local drafting office to satisfy its own requirements. Where a saving of considerable time is the result abbreviations of special application may be added to the list of Fig. 9 for one's own use. However, before this is done consideration should always be given to the question of whether or not the new abbreviation will conflict with one of the old ones, and whether or not it will tend to confuse, rather than to assist, some outsider. It is always good practice to spell out, in full, on sheets which will go outside of the concern, any group of words the abbreviation for which might tend to confuse.

FULL-SIZED SHIP EXPERIMENTS

By M. M.

Numerous cases are on record where good results have been obtained by alterations made to full-sized ships after they have been completed. Trial trips have been run both before and after the alterations, and in this way a trustworthy estimate has been made of the difference in performance.

At the spring meetings of the Naval architects in 1917, Sir E. Tennyson d'Eyncourt, for instance, recalled the case of two ships built about 17 years ago. After they had been in service for some time he suggested that the bossing, which was nearly horizontal, was not at a suitable angle. On one of the ships coming back to the works it was, therefore, decided to alter the angle to something approaching 45 deg., and in addition, the casting was fined at the aft end as well as the lines of the bossing itself. At higher speeds much better results were obtained than with the old horizontal bossing, but the improvement did not maintain itself at lower speeds. This showed that the improvement was due to the angle of the lines. After the ship had been on service for some time it was found that so much coal had been saved, that her sister-ship was sent to have a similar alteration made to her bossing.

Sir Archibald Denny, at the North-East Coast Institution of Engineers and Shipbuilders, in November, 1915, instanced a rather curious case of alterations made to a full-sized ship, where it was found that the bad performance of the vessel was not due to the suspected cause, but to something entirely different. When the vessel was built, her bilge keels, which were very long, were not put on normal to the bilge, as they would have gone out of water at the ends, the angle of the diagonal plane of the keel being reduced. When the vessel was tried on the measured mile, her efficiency was found to be very low. Someone suggested that the bilge keels were the cause of the trouble, and a length of 20 feet was cut off from each end of both of them. This causing no appreciable difference, the bilge keels were taken off altogether, and the reduction in the resistance was found as nearly as possible to be quite normal. Later it was seen that there was a lack of surface in the propellers, and when new propellers were put on, the efficiency came up to expectations. This, however, did not explain the fact that in an almost identical ship with similar propellers, proper results have been obtained, and Sir Archibald Denny has stated that to this day he is not able to explain with certainty why the results were so different. Another case quoted by him was that of a Channel steamer. In order to get the maximum result, mastic was placed behind each butt and washed off into the general surface, and this was done for some years. But when the mastic cracked off it was not replaced, because there was no apparent differences in the speed on service with or without it.

Admiral Taylor, in his "Speed and Power of Ships," refers to the steamer Niagara, as a yacht about 250 ft. long, in which the shaft brackets were nearly horizontal. She was given two six-hours' trials under similar conditions. In the first, the screws were inward-turning, and in the second were inter-changed to be outward-turning. The horse-power developed on each trial was very nearly the same, but with the inward-turning screws, the average speed was 12.8 knots, whereas it was 14.12 knots with outward-turning screws.

Captain Dyson, the propeller designer to the American navy, has instanced a case of two oil-fuel barges built for the Navy Department. These vessels were designed for a speed of six knots, and everything indicated that the speed could be easily obtained with the power. After trying several different propellers, however, the highest speed realized was only 5¼ knots. It was thought that the action of the water indicated that a portion of the feed was being drawn from astern, and as the cheapest remedy, the line of shafting was changed so as to lower the propeller about 3 ft., although the lower blade projected below the line of keel. In this new position, with propellers of the same pitch and surface, but of 5 in. greater diameter, a speed of 6¼ knots was obtained with the same power as before. The greater portion of this increase in efficiency of the propeller was due to increase in diameter, and the remainder to the change in position, but the increase in diameter was rendered possible by the lowering of the shaft.

Many other examples could be given, but those mentioned are sufficient to show the benefits that may be derived by making alterations in consequence of careful observations of a ship's behaviour in service. The cost of carrying out the alterations must vary, and in some cases will no doubt amount to a fair figure. On the other hand, the large saving brought about by the reduced fuel consumption, which operates during the whole lifetime of a ship, will more than balance even a considerable outlay on such alterations. When it is generally realized, it can be confidently stated that enromous economies will be effected in ship propulsion.

WHY IRON CHIMNEYS CORRODE

The cause of corrosion of galvanized-iron extensions to chimneys is laid generally to condensation, which forms inside the stack, and which, in conjunction with the carbon, which has been deposited in use, creates a galvanic action, which soon destroys the zinc coating, and finally eats through the iron or steel base. The prevent the condensation, an air space around the stack is recommended. The stack is made double from the base to a point close to the top, with small iron braces between the inner and outer castings. These may be riveted close to the ends of the sheets in course of construction. The air space may be one or two inches, according to the size of the smokestack and local conditions. —M. E.

A Handley-Page airplane took up forty passengers the other day, according to London copyright dispatch to the "World." This giant bombing machine, which is the biggest in the world, weighs six tons, and a total weight when fully loaded of 15 tons.

The Training of Engineering Apprentices

Necessity of Training—Standard of Elementary Education Required—The Apprentice From the Employer's Point of View—A Suggested Course of Training—An Apprentice Club in Scotch Engineering Works

By T. H. FENNER, Associate Editor

THE happy turn of the world's wheel that brought in sight the end of war, has concurrently turned men's minds to the vista of peace, with its obligations and rewards. With reference to this an important announcement was made recently by a minister of the Government, concerning the efforts the Canadian Government is about to make, or is making, to provide a merchant fleet. Thirty-one steamers, varying from 4,000 to 10,000 tons, are to be built in Canada, and presumably all the boilers, engines, etc., will also be built in Canada. This is an auspicious event, coming, as it does, at a period when the emergency work of the new Canadian industry was about all over, and the immediate future a matter of doubt. There is every prospect that we shall have a permanent shipbuilding and marine engineering industry, and now is the time to look to securing the supply of men to keep it going. The professions intimately connected with shipbuilding are of the naval architect and the marine engineer. The trades connected with it are legion, some of them highly skilled, some less so. The naval architect is purely a highly technical personage, connected only with the more complicated features of ship design, stability, etc. With him we are not concerned in this article. Neither need we here consider the plumber, steamfitter, electrician, plater, riveter, joiner, carpenter, etc. These are all trades that are in much request in ship construction, but they are trades, and can never be professions. The marine engineer, unlike these, has it entirely within his own power to remain a tradesman or become a professional man. I say, entirely within himself, but that is not strictly correct. It could be more truly put if I say, according to the opportunities afforded him in his apprenticeship days, coupled with his own ambition. Canada has not in the past resorted very much to the apprenticeship system to produce tradesmen, and it may be said that she has not produced tradesmen to any great extent. If marine engine building is to grow to a real industry, then marine engine builders must be trained to enable them to build engines in competition with nations who have a supply of expert tradesmen always on hand. This training must be got systematically, over a sufficient number of years, and under conditions that will enable the neophyte to register a steady progress. During this time his technical education can be looked after and arranged according to capacity shown, so that at the end of his apprenticeship it is quite plain as to whether a tradesman or an engineer has been developed. The question of the best way of achieving these results has been the theme of much discussion, especially in Great Britain, where the apprenticeship system is very fully developed. There has been much difference of opinion expressed among the men at the head of the marine engineering profession, and it must be remembered that these men are the products of the apprenticeship system, sometimes coupled with a university course, but just as often with technical education obtained in evening classes. In this country the big railway shops have developed a system of training apprentices on railway work, and giving them some technical education at the same time, which is a step in the right direction, but naturally, these boys are developed chiefly for railway practice, to become locomotive experts, qualified to be superintendents of motive power, etc.

Standard of Education Necessary

In the first place, before a boy is admitted to an apprenticeship at all, some recognized standard of education should be required. A boy who has attained the age of 16, which he should have before entering the engineering profession, without having a thorough grounding in arithmetic, including algebra, up to quadratic equations, and a good grounding in geometry, coupled with the ability to speak and write good English, is handicapped in the beginning. He is not handicapped in so far as becoming a tradesman goes, but he has a lot of leeway to make up if he is going to become an engineer. The reader may think that a good deal of stress is laid on the terms tradesman and engineer, but this is really necessary, as there is a tendency in Canada to include in the term of engineer everyone from the man in charge of a fried potato cart to the designer of the Quebec bridge. A marine engineer, in the strict sense of the term, is a man who can design, build, and operate a marine power plant, and in virtue of these attainments he is a mechanical engineer. A man who, as is often the case here, graduates to a position in charge of engines through the stoke hold, greasing, etc., is not an engineer. He may be competent to exercise supervision over a set of engines in the same sense that a locomotive driver does, but of the principles and underlying science that those engines are constructed from, he is unaware. This is not his fault, as he has never had the opportunity to acquire such knowledge, and too often, not the elementary education necessary to grasp the opportunity had it presented itself. The same man, if taken from his engine room and put in an erecting or fitting shop, would be of no use except as a laborer, as he has never learnt the trade. Yet he rejoices in the name of a marine engineer.

The Apprentice From the Employer's Standpoint

In discussing the question of apprentices, it is often considered merely from the view of the future prospects of the boy, the firm he is apprenticed to being considered only as a means to an end. Too often the boy himself gets the view, which is bad for him and for the firm. While most employers are only too glad to help apprentices along and offer them opportunities for acquiring the technical side of their work, they cannot be expected to form a secondary education body, which pays for the privilege of teaching. In direct opposition to this idea, many engineering firms in the United Kingdom only took apprentice engineers on payment of a heavy premium, and in return undertook to educate them in their profession. Their other apprentices were apprenticed to fitting, turning, pattern making, as the case might be, but were distinctly tradesmen. This is the supply that the country had to draw from for its working forces. Some of these boys, by industrious application in their own time to technical classes, became qualified for better positions, and some of them rise to high positions. However, it was strictly their own effort. It must be always borne in mind that an apprentice is a source of expense to his employer for the first two years, no matter how good he may be, or how anxious to learn. When he has been three years, the employer begins to get some return from him. After his five years are completed, he usually leaves to get experience of some other shop, or more money, so that any expense put into his training by the employer does not come back to them direct. However, they get the benefit of a continuous supply of labor, which is necessary for carrying on business. There is another benefit in that every apprentice who leaves a shop and becomes a successful engineer, is a perpetual advertisement to that shop, and bearing, as he usually does, an affectionate remembrance of the place where he learnt his business, will reciprocate by placing business their way whenever possible. It may be accepted that, in the larger sense, it is well worth while for the employer to make an effort to encourage his apprentices to acquire knowledge, and to pick out the best according to ability shown, to become eligible for staff positions. A standardized system for all shops would go a long way to help in this effort.

Suggested Course of Training

As a general rule, marine engineering apprentices have always in view, spending some period of their lives at sea, and qualifying for the certificates of the Board of Trade. Probably 75 per cent. of them do actually go to sea for a varying period, according to how the life strikes them, or to their ability to pass the examinations. A considerable number choose this as their life's work, and remain at sea, rising in their profession till they are chief engineer of a large ship. There is no finer class of man afloat or ashore than the marine engineer, and he is generally a well-informed man technically, besides possessing marked mechanical ability and a profound knowledge of boilers, engines, pumps, under hard working conditions, coupled with a perfect knowledge of their construction. Other men, after a few years at sea, enter the service of Lloyd's or the Board of Trade, as surveyors, a position they are well qualified for.

Superintendent engineers of steamship lines, works managers, consulting engineers, are all positions open to the marine engineer who is ambitious. It is, therefore, necessary that the apprenticeship period should cover enough time in the shop itself to allow a thorough grasp of the elements of the trade to be obtained, as well as to have the necessary shop service to qualify for the Board of Trade examinations. The Canadian Government examinations are modelled on those of the Board of Trade, and the Board of Trade certificate is valid all over the Empire. It is on the question of technical instruction during the period of apprenticeship that the differences of opinion are felt. The opponents of the evening technical class method hold that a boy of 16 to 21, who has worked hard all day, is in no fit condition to receive instruction in difficult technical subjects at night. They hold that technical instruction should be imparted during the day. The upholders of the evening class claim that to give technical education during the ordinary working hours, means disorganizing the work of the shop, and prevents the boys getting the class of work they would wish. This is because the best jobs cannot be left standing while the boys attend classes. For those boys whose parents have the means, the ideal way would be to attend the university courses while in session, and devote the remaining time to the shop. The boy following this plan does not become an expert tradesman, but after all, why should he? As long as he acquires the knowledge of how a thing should be done, and the best way of doing it, that is what he will require to round out the technical knowledge required from his university course. Most of the boys following this course of training are destined for staff appointments, and that is what their training fits them for. To come back to our average boy, what is the best course to pursue to benefit himself, his employer, and produce the best men for the engineering trade and profession? If the boy comes to his apprenticeship with the educational acquirements referred to earlier in this article, the necessity for some of the classes attended in the first two years is eliminated. In fact, classes to teach elementary mathematics should not be required in an evening school, as every boy should be kept at school till he has received that instruction. Therefore, let the first year in the shop be devoted to, say three months in the tool stores, getting familiar with the various tools in use before going out in the shops to use them, and the remainder of the time in the fitting shop. The evening class should be confined to acquiring the elementary course in machine construction and drawing. In a shop employing enough apprentices there will be some one man in charge of them, and looking

FIG. 1—READING ROOM AND LIBRARY

FIG. 2—A CORNER OF THE STUDY

FIG. 3—RECREATION ROOM

FIG. 4—GYMNASIUM

after their welfare. If not, the boy's immediate foreman may be depended on to observe his progress. By this time he will have become sufficiently acquainted with the use of his tools to be entrusted with small jobs, and what he has learned at his drawing class will give him an intelligent interest in what he is doing. The second year should be still in the fitting shop, and the evening class work extended to take in trigonometry in addition to the second year machine construction and drawing. At the end of the second year his capabilities as reported by the foreman, and the results achieved in his evening class, should be such as to entitle him to a period on the marking off table, where his knowledge of reading drawings can be put to practical account. This marking off table work is excellent training. After three to six months of this work he should be moved to the erecting shop, where he will combine his knowledge of fitting, with his ability to understand a drawing, in the fitting up of the completed article. His evening classes during this year should include the study of physics relating to the heat engine. At the end of the third year an examination should be held by the firm, covering all the shop experience and technical education received up to date. If the candidate shows sufficiently well in this, he should be admitted to the drawing office, and during the next two years should be given the opportunity to attend advanced technical courses in the day time, either held on the firm's premises, or at the local university or technical college. During this time he will have occasion to visit ships under construction, and under repair, and his knowledge will enable him to grasp the essence of what he sees. At the end of his apprenticeship, if he elects to stay awhile with the firm, they will have a useful man. If, as is most likely, he moves to another firm, or takes a few years' seagoing experience, he has the necessary equipment to become a success. For the boy who does not qualify there still remains a chance. He should pursue his technical studies in the evening, and his shop work will be according to what he shows himself good for. At the end of his fourth year he may be given another opportunity to enter the drawing office. That would still give him a year, and a very useful year. If he does not succeed then, he has still the technical schools to go to. At the end of his apprenticeship he will be, in most cases, an excellent tradesman, with a fair technical education. He may go to sea and become a first class man. He may elect to remain at his trade ashore and work up to a general foreman or superintendent. The fact of him not passing the examination does not condemn him, but merely ensures that the boys of real ability will get their chance. At the least, he becomes a tradesman capable of earning a comfortable living, and by his skill and ability in this direction, helping on the industry of the country.

In connection with this subject the accompanying illustrations show what is being done in Great Britain to encourage the boys to be interested in their work. The recreation rooms shown here are in the works of Scott's Shipbuilding and Engineering Co., Greenoch. The fee for membership in the club is one shilling or 25 cents per annum. It is open every evening except Sundays, and the proceeds of the subscriptions are presented annually to the local infirmary in the name of the club. One of the staff is present every evening to assist any boys who wish to study their homework connected with their technical classes, and there is also a physical instructor in the gymnasium. There is a corner containing lathes, etc., and any boy who wants to pursue a hobby is allowed the use of these tools and scrap pieces from yard and foundry are furnished them to practise on.

A 17-FT. CAST IRON FLY WHEEL

By F. C. P.

The accompanying illustration shows a 17-ft. cast iron fly wheel for an electric motor driven rolling mill as constructed at the West Homestead Mesta Works near Pittsburgh, Pa. This speci-

17-FT. CAST IRON FLYWHEEL

ally designed fly wheel, running two miles per minute is made of cast iron sections bolted together as indicated in the photograph. As it runs at a rim speed of 10,000 feet per minute, the wheel is made of air furnace cast iron, which has a much higher tensile strength than ordinary cupola iron to withstand the forces of this high speed.

THE RELATION OF AVIATION TO SHIPPING

Without merchant shipping it would be impossible to carry overseas commerce. Our overseas commerce will be vastly improved by the addition of aviation. Within a very short space of time after the war we shall find all the principal mail liners fitted with seaplanes. Considerable time will be saved in the transit of mails.

A liner leaving New York with urgent and important letters will be able to discharge them by seaplane, 300 to 400 miles west of the Irish coast; within a few hours they can be delivered in London, thus effecting a saving in time of 24 hours. The same procedure can be carried out by a vessel bound to New York—weather, of course, being an important factor—for in fine and settled weather a well-equipped plane would travel at an enormous speed over a considerable distance. It is quite within the bounds of possibility that letters posted in London can be delivered in New York within four days.

At the outset of this service, which will, no doubt, be subsidized by the governments of both countries, a special charge, say, of 2s. 6d. to 5s. per letter could be made on all trans-Atlantic communications marked "Urgent. Per Aerial Post."

The splendid liners of the Royal Mail Steam Packet Company will in all probability carry seaplanes for the rapid dispatch of the South American mails. Letters posted in Santiago de Chile, via Buenos Aires, could be put on board Royal Mail Steam Packet, and discharged by plane 300 miles south-west of Gibraltar or Lisbon, then transferred to the Transcontinental Aerial Mail. In the same way, London letters marked urgent could be discharged 300 miles north-east of Buenos Aires.

P. and O. liners would find the seaplane of great value in accelerating the delivery of mails to and from the East. The flat island of Perim, known to mariners as the "cinder heap," would make an admirable landing for planes—letters to Europe could then be transferred to another plane and delivered at Port Said. From there they could be reshipped to the Mediterranean aerial mail.

There are four-engined flying machines capable of developing close upon 800 horsepower, flying at a speed of over 160 miles an hour, and soaring to a height of 27,000 feet.

Wireless telegraphy will take an important part in the dispatch of these rapid mail services. The time of the seaplane leaving a vessel and its progress in flight can be transmitted to the position of its destination.

The amazing manner in which the modern aeroplane has increased man's mobility is shown by the fact that a pilot breakfasted in Newcastle, lunched on the south coast, had tea in France, and dined in London.

At the termination of hostilities, thousands of seaplanes will be liberated for commercial purposes—they, and many more, will be required for mail services throughout the Empire.

Nearly 5,000 workmen earning $57 to $60 a week on government construction in Brooklyn, N.Y., have gone on strike and refuse to return unless the order issued by Secretary of War Baker, cutting off all overtime and pay-and-a-half for Sunday work is revoked.

Testing Machines in Industrial Laboratories

The Wise Purchasing of Engineering Materials is Dependent Upon Specifications Properly Controlled by Analysis and Test

By H. S. PRIMROSE, Messrs. Crittal Mfg. Co.,
and J. S. GLEN PRIMROSE, Messrs. Ransomes & Napier, Ltd.

AT no previous time have engineering firms been called upon to do so much physical testing as now to ascertain the suitability of their products, and the privilege has not been given to many of finding themselves efficiently equipped and staffed to undertake the work in their own laboratory or testing department. It has been the great privilege of the writers to be associated for some time past with firms of which the managing directors have been sufficiently broadminded to assist their neighbors in the making of tests, and they venture to claim that not only is this action much appreciated by those concerned, but that the efficiency of the area has been considerably increased in consequence of the advice secured. The authors take this opportunity of thanking Mr. F. H. Crittall, of Messrs. Crittall Mfg. Co, and Sir Wilfred Stokes, of Messrs. Ransome and Rapier, the managing directors of their respective firms, for permitting them to place before the Institute the firsthand descriptions of the several testing machines employed in their laboratories, and also of some of the interesting data obtained by their use. The prime considerations which caused the selection of most of the machines described were their moderate cost and short time of delivery, and other, but no less important points, were their simplicity and convenience for commercial testing, combined with the accuracy of their determination of the various physical properties of metals. The article is published through the courtesy of "London Engineering."

Tensile Testing Machines

Whilst for a long time we have been almost exclusively confined to the use of lever machines in this country, the use of lever testing machines has been almost entirely abandoned on the Continent, and also to a large extent in America. The hydraulic method of applying the load is nearly universal, but in most cases an independent system of measuring the stress is necessary, and few rely wholly upon the simple pressure-gauge method for accuracy and continued reliability. One class of machine is so designed that the application of the load and its simultaneous measurement is accomplished by the same pressure system, and this, of course, constitutes a very simple, convenient and compact machine, which has no knife edges or springs to go wrong, and is further entirely free from inertia effects which are so fruitful a source of error. This principle is adapted to the vertical form of testing machine by Messrs. Amsler Brothers, of Switzerland, and their combination of press and pendulum gauge is recognized by the Association of Testing Materials as universal; it is constructed in a variety of sizes and standard forms. Their 1916 model of 30-ton universal testing machine is shown in Fig. 1, and this has the various arrangements whereby round, flat and headed test bars may be tested in tension; it enables bending, transverse and compression tests to be performed, and by means of easily adjusted bolsters it permits hardness, shearing, or punching tests to be made with the minimum of trouble.

The entire machine comprises three parts, the first of which is the press with a steel ram operated by compressed oil. The fit in the cylinder is sliding, so that friction is negligible owing to the small constant stream of oil escaping while the machine is at work. The pressure of oil is conveyed from the ram through a cross-head with a hardened steel socket, to two steel bars freely supporting the cradle or moving head. The crown is secured to the base by four stout steel bars which support the superstructure, and these endure the maximum load of the machine without appreciable deformation. The base itself is a hollow iron casting with a steel table to anchor

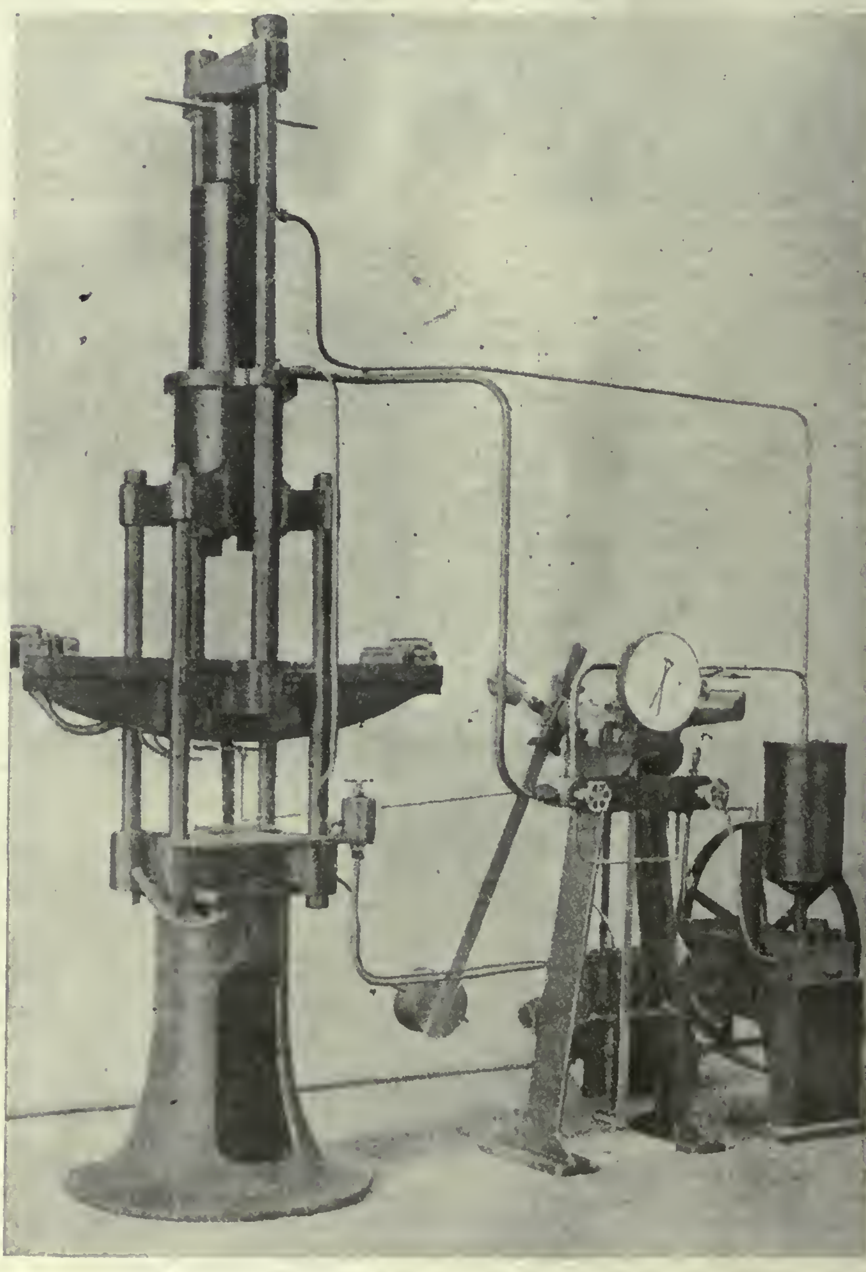

FIG. 1—30-TON AMSLER UNIVERSAL TESTING MACHINE

the wedge grips or other shackles, and no great strength is required in this stand as it supports no part of the loading, nor does it require to take any overhang since the centre of gravity is not moved during the conduct of the tests. Tensile and shearing tests are made by securing the test bars between the base and the cradle, and compression, punching, bending and transverse tests are made between the cradle and the crown without any elaborate fittings. To raise the moving head to any required position the pressure oil is admitted by the valve at the right of the press, and to lower it again by gravity it is sufficient to open the release valve on the pressure gauge, and let the oil return to the reservoir in the pump.

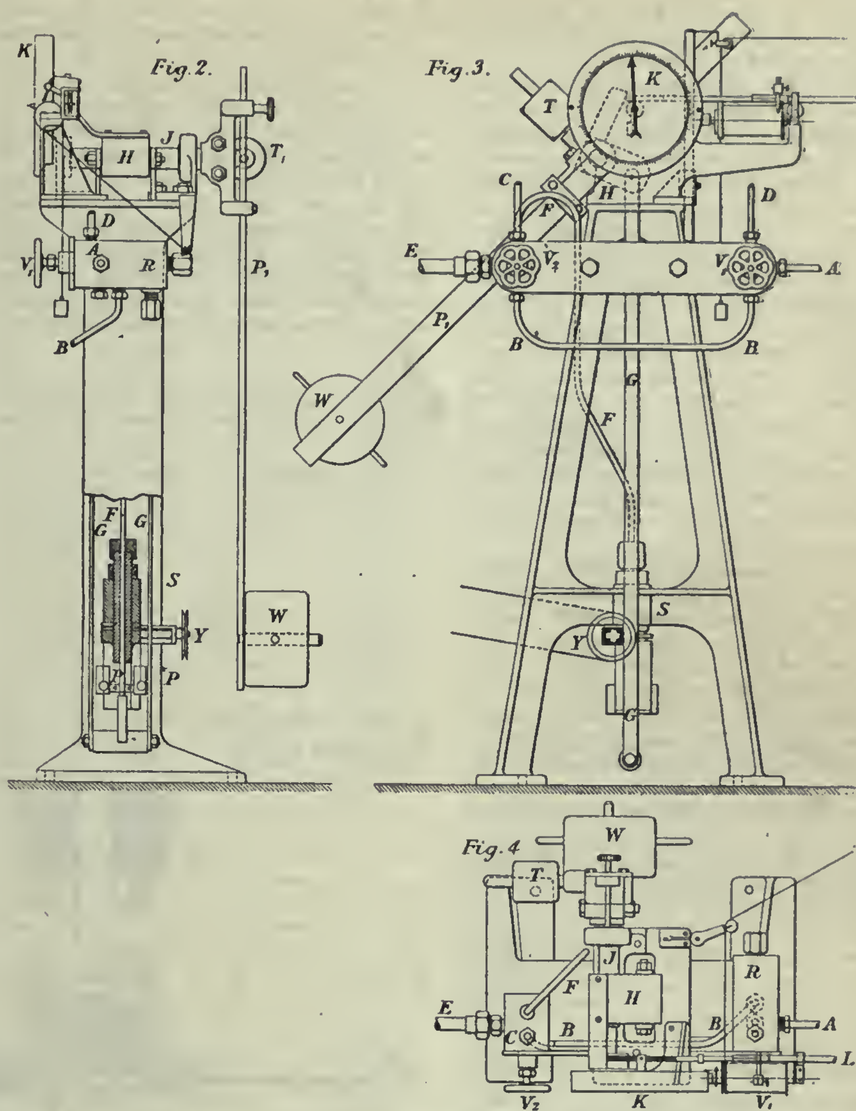
Oil Pump

The high-pressure oil pump is the second part of the apparatus, and it may be driven by either belt or motor. The oil supply is delivered by three pistons at a steady pressure up to 3 atmospheres, and the suction valves are controlled by a handle which lets the motor run light when in the "off" position, but forces oil through the pipes when in the "on" position. If all other valves in the pressure gauge and press are closed, then the oil is simply short-circuited by a spring-controlled valve, back into the reservoir.

The third part of the assembled machine is a simple and accurate form of direct-acting pressure gauge or pendulum manometer, which measures the force exerted on the test piece by the oil pressure. This it does by displacing a freely hung pendulum from the vertical position so that the pointer of the gauge constantly indicates the force exerted by the automatic balance effected by the pendulum. Details of the pressure gauge and regulators are shown in Figs. 2 to 4. Pressure oil enters by pipe A, and may be short-circuited by a spring at the back of the regulator R into the pipe B, and large return pipe C communicating with the oil reservoir. On opening the valve V_1, oil flows by the uptake pipe D to the cylinder of the press, and thus elevates the ram. The release valve V_2 on the left of the manometer puts the pressure pipe E into communication with the return pipe C. When load is placed on the specimen the oil pressure is conveyed by pipe F to the small cylinder S, which causes the piston P to move without friction due to its rotation and the slight escape of oil. The force which expels the piston P is transmitted to the two vertical rods G bolted together by a distance-piece at the bottom, and attached to a short block lever H at the top through ball bearings. The movement of H causes the shaft J, mounted in the manometer frame with ball bearings, to rotate and deflect the pendulum from its normal position till it assumes a position of equilibrium. The pendulum rod can be suspended from several different points, giving a variation in the sensitiveness of the machine.

Record

Sensitive records of the variations in the loading of the test bar are secured in a unique manner. Attached to the front end of the rod J is a short steel arm parallel to the pendulum, and moving against a screwed rod L, which not only actuates the pointer moving over the scales of the dial K, but also carries a sliding pencil holder. The tracing pencil moves over the diagram paper clipped on to the brass drum which rotates smoothly when actuated by the chord from the extensometer attached to the test bar. With short bars it is often sufficient to take the travel of the cradle relative to the base for commercial purposes, and this also saves the removal of the extensometer prior to rupture of the bar. When the bar breaks the pendulum falls back freely for but a short distance, as the oil escaping from the cylinder S has to do so by a small by-pass so that the motion is comparatively slow and without jerk. Although the pressure gauge is so sensitive there are no weak parts in it to go wrong, as it is throughout of the most robust construction, and yet it is not unwieldy. It simply requires to be bolted to the floor sufficiently level to let the pendulum swing in a perfectly vertical plane. The rotation of the screwed rod L, whilst holding the pencil carrier, enables the pointer to be readily adjusted to zero at any time. Measurements on the autograph diagram are facilitated since the complete rotation of the pointer over the scale gives a travel of 10 cm., corresponding to the maximum load for each sensitiveness.



Figs. 2 to 4. Automatic Pendulum Pressure-Gauge used with Amsler Testing Machine.

Other Tests

To make transverse or bending tests, two roller supports are fixed at a convenient distance apart in the cradle by means of the side screws which engage the cross bars sliding in a slot which runs the full length of the cradle on each side. The middle support to apply the bending, is suspended by a pin let into the side of the crown, and this only requires to be withdrawn to let it fit into a slot encircling the head of the support. This may be provided with a roller like the side bolsters, or it may be simply a rounded die to effect the bending test when the supports are moved into close proximity. The centrally-held die may be provided with a spring clip holding a 10 mm. ball to perform Brinell hardness tests when the cradle is raised with the specimen to effect the compression.

Compression tests are very simply made on test pieces placed between two

cylinders, the test-piece can be readily inserted and sheared without any considerable amount of bending such as usually accompanies this test.
hardened steel discs, one of which is held in the middle of the cradle by a square foot-step, and the other is supported from the centre of the crown by a circular bolster provided with a spherical seating to ensure the crushing faces being parallel. Crushing tests are now more commonly specified than formerly, and interesting results are often obtained with metal which have been variously heat-treated and worked, as shown in Table I. The first section shows the toughening effect of oil quenching upon a medium carbon steel for power press screws, the second deals with the forging of ordinary cast-iron between dies in the press, and the third part shows how much even the strongest brass may be improved by mechanical treatment at the right temperature.

For making shearing tests, special yokes are fixed by the cross bolts through the baseplate and the cradle. These two portions are provided with hardened steel cylinders with a hole through each for carrying the test bar. Accurate alignment is secured by screwing up collars at the end, thus preventing any play between the shearing faces. By selecting a test bar diameter nearly equal to the central opening in the hardened

Values given are the average of four tests.

Punching tests also give useful information as to the behaviour of metal under other stresses, and it has even been claimed that this test gives a better average value from which the tensile result may be calculated than the direct tensile test itself, since the latter deals with a much smaller section than that cut by the punch. The punching test as performed in the compression part of the testing machine only requires a simple bolster to carry the punch and die in correct alignment, and to withdraw the punch without displacement of this after the flat test piece has been pierced. Several corresponding values of the ultimate tensile, punching and shear stress of several grades of steel are given in Table II and show that simple relationships can be established between these values.

TABLE II—Relationship of Tensile Strength with Punching and Shear Stresses for Various Steels.

Average Tensile Strength.	Actual Punching Stress.	Shearing Stress.
tons per sq. in.	tons per sq. in.	tons per sq. in.
21.3	18.3	10.1

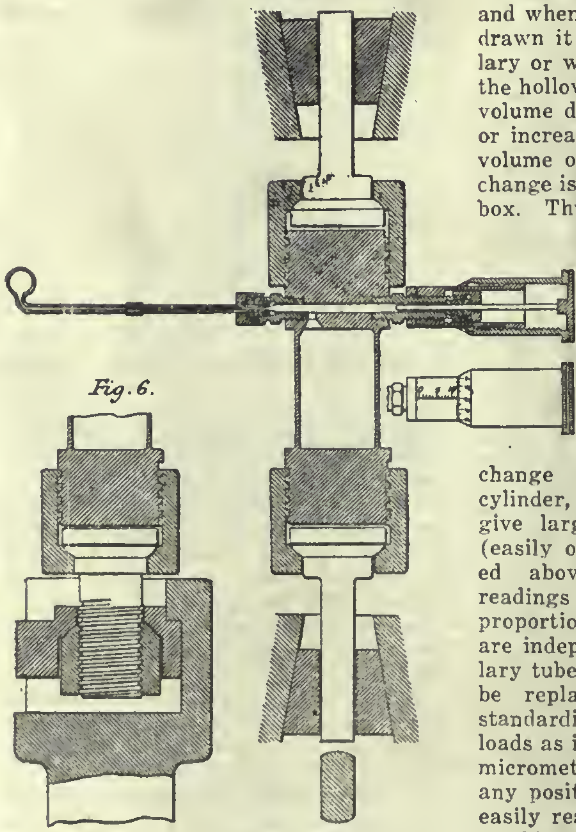
"T"	0.65 T + 3.18	0.35 T + 3.0

When autographic diagrams are taken of the punching and shearing tests, valuable information is got as to the practical value of the metal, its ductility and behaviour in practice. The yield-point in shear stress is easily observed and serves to place the metal in the class to which it belongs.



FIGS. 5 AND 6—AMSLER STANDARDIZING BOX

Standardizing

Even although it is usual for each testing machine to be securely calibrated by the makers and guaranteed to be correct, it is usually advisable to check them occasionally to ascertain if there is any variation during service. To do this, it is sometimes considered necessary to lift standard weights on the testing machine itself. Otherwise a standard bar of known modulus of elasticity may be submitted to tension within its limit of proportionality, but this necessitates precision instruments to measure the deformation. The crushing of a number of small copper cylinders of known reduction of length for a given load may be adopted, but no very great accuracy may be expected from this method. To overcome these difficulties Messrs. Amsler have invented an ingenious standardizing box which is light and easily handled. It can be used without expert knowledge to check testing machines either in tensile or compressive stress, both quickly and with as great exactness as by the dead-load method.

As shown in section in Figs. 5 and 6, the box consists of a hollow cylinder of special steel filled with mercury which extends into a horizontal capillary glass tube projecting from the box. The tube is provided with a zero mark to which the mercury is adjusted by a micrometer screw, the stem of which projects into the enclosed space filled with mercury, and when the screw is advanced or withdrawn it pushes mercury into the capillary or withdraws it into the box. When the hollow cylinder is stressed axially the volume decreases under the compression or increases under tension so that a volume of mercury equal to this volume change is expelled from or pulled into the box. Thus the micrometer handle must be turned to restore the mercury to the zero point in the capillary tube, the bulb at the end of which holds any excess and prevents its escape. The scale on the micrometer enables the observer to read hundredths of a turn of the handle, and this gives a measure of the change of volume of the steel cylinder, which being thin-walled to give large displacements of mercury (easily observed), must not be stressed above its elastic limit. The readings of the micrometer which are proportional to the loading of the box, are independent of the size of the capillary tube, so that if one is broken it can be replaced by another without restandardizing the instrument by dead loads as is done in the first instance. The micrometer can be turned at pleasure to any position so as to admit of its being easily read when in place in the testing machine. In making compression checks, it is necessary to ensure that the box is placed between two perfectly flat surfaces parallel to one another in the extension boxes for tensile standardizing crown and cradle of the machine. The have screw heads with extension pieces to be gripped either in the wedges or in the spherical seatings of the other shackles. These boxes are made in two forms, one for measuring compression only, and the other for either extension or compression, the former ranging up to 120 tons, the latter up to 30 tons. To convert the double-purpose boxes from tensile to compression use, it is only necessary to screw off the heads of the end extensions. As the constants of the micrometer readings for compression differ slightly from the same stress readings in tension, the two sets of constants are stamped on the boxes.

Torsion Testing Machines

The importance of this useful method of determining the shear strength of metals has been recognized only comparatively recently, and although many forms of lever machines have arrangements for carrying out this test and for measuring the torque, it is still not a common test to be made commercially. Some of these machines have been fully described by Hailstone in vol. xxviii of the Staffordshire Iron and Steel Institute proceedings, but there is a simpler way of measuring the torque than by means of the customary lever. The balancing of the twisting couple produced lends itself readily to the use of the pendulum pressure gauge, and Messrs. Amsler make several types of machine in which this principle is used. The smaller hand size for torsion testing alone is illustrated in Fig. 7, which shows the machine to consist of a rigid frame with two heads, the fixed one for applying the torque, and the other moving on ball bearings and carrying the pendulum. The bar to be tested is screwed in jaws in the two heads, which take flat bars or rounded ones if provided with rectangular heads. The torsion couple is produced by a pulley driven by belt or worked by hand, and the rotation is transmitted to the test bar by worm and wheel. The pendulum, suspended from the moving head by an axis which rotates in ball bearings, serves to balance, by its inclination from the vertical position, the torque developed in the test bar. The weight of the pendulum bob is easily changed by removing parts of it which are bolted on, so that the sensitiveness of the machine can be increased by diminishing the maximum torque from the full 150 kg.-m. (say 1,100 lb.-ft.) to 100 kg.-m. and to 50 kg.-m. The angular displacement of the pendulum in conjunction with the angle of twist of the test bar gives a means of autographically drawing a diagram of the test. The movement of the pendulum-carrying head along the frame of the machine prevents the test bar from being subjected to the slightest tension as it shortens under the twisting it receives.

Messrs. Amsler make combined tension and torsion machines which may be made to exert a tension of 30 tons or 50 tons simultaneously with or separately from a torque of ½ ton-ft. or 1 ton-ft. The tractive force is applied hydraulically by oil under pressure, but the twisting movement is applied by hand through gearing. The base of the machine is not fixed as in the universal machine, but may be moved up or down to the required position along the four supporting rods, by means of a hand screw. The cradle or moving head carries the fixed end for the torsion test, the lower grip in the base being made to revolve centrally. To balance the torque use is made of the oil pressure set up in two cylinders situated horizontally in the crown of the machine. The pistons working in these cylinders act as pumps, and the resulting pressure is conveyed by a pipe to the registering pressure gauge. The tension and the torsion pressure gauges are set on the one stand, side by side, so that they can record their respective diagrams on the same sheet of paper clipped on the drum. Instead of the ordinary pendulum gauge, the manometer used in this instance is usually the laminated spring type. This form of spring manometer is capable of accurately indicating and registering rapid changes in the stress applied. The oil pressure from the cylinders passes by the several tubes to their respective gauges, and by pressing upon a piston moving without friction in a small cylinder, causes two leaves of the laminated springs to be pressed closer together. A fine-toothed rack engages a small pinion in the centre of the indicator dial, and causes the pointer to move round the scale. By attaching different weights to the underside cross-head of the gauge various sensitivenesses can be registered in order to have an open scale for each reading. The balancing of the different stresses exerted on the test bar is thus automatically effected, and it leaves the operator free to perform the complex test, since after he has started the tension force by admitting the pressure oil to the top cylinder, he can give his attention to the application of the twisting couple by hand, the diagrams being autographically produced.

(To be continued)

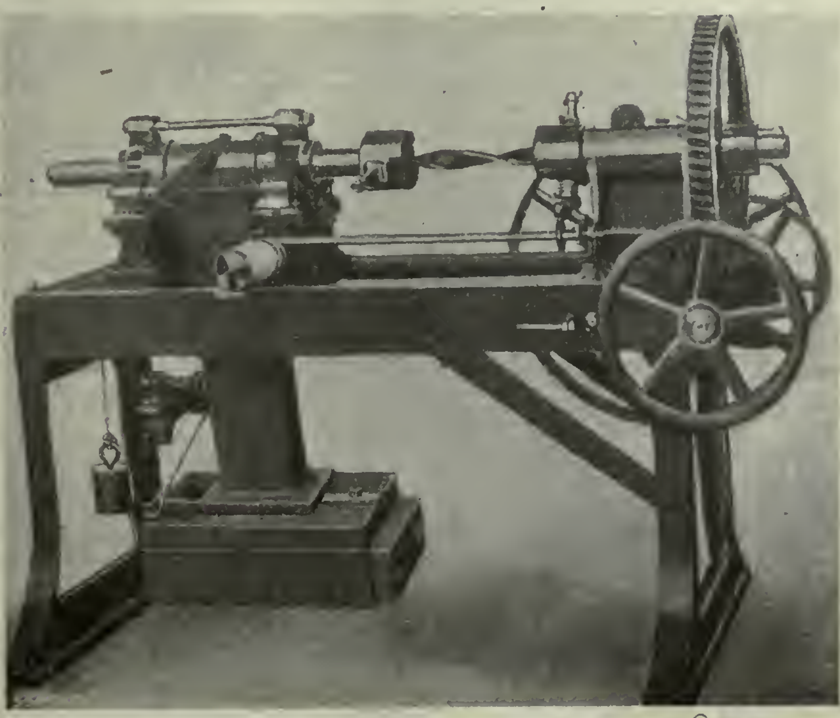


FIG. 7—AMSLER TORSION TESTING MACHINE

DESPISED EVEN BY HUNS

German Prisoners Struck Rather Than Work With Cowards.

A remarkable incident occurred (says the Central News) at a camp in the south of England, where a large number of German prisoners are engaged in making roads. In order to facilitate the progress of the work a number of conscientious objectors were detailed to assist the prisoners. Upon their arrival the German prisoners struck work, and a n.c.o. delegated to speak to the officer in command, said: "We have struck work. These men are conscientious objectors and won't fight for their country, and we won't work with them. Let them go and fight, the cowards." The officer tried to reason with the "delegate," but the latter said it was no use, they could punish him and the others if they liked. Indeed, they would accept any punishment, but they would not work with conscientious objectors. Eventually the C.O.'s were withdrawn, and the strike ended.

A well-known Scottish architect was once travelling in Palestine, when news reached him of an addition to his family circle. The happy father immediately provided himself with water from the Jordan to carry home for the christening of the infant, and returned to Scotland. On the Sunday appointed for the ceremony, he duly presented himself at the church and sought out the beadle, in order to hand over the precious water to his care. He pulled the bottle from his pocket, but the beadle held up a warning hand, and came nearer to whisper: "No the noo, sir," he said, "no the noo. Maybe after the kirk's oot!"

You can't succeed if you don't take pleasure in your work for its own sake. And if you are fitted for it, you will.

WELDING AND CUTTING

The Development of Electric Welding

The Author, in a Paper Read Before the A.I.E.E., Outlines the Present Status of Electric Welding—The Use of Alternating Current—Methods of Electric Welding and Future Developments

By H. A. HORNER

THE two main processes of electric welding, namely, arc welding and spot welding, were found by this committee applied in the first case to repairs and in the second case to certain factory quantity production jobs. The work done was in the case of spot welding only on light material, and in neither case very extensive. The processes to be successful in their application to the construction of merchant vessels would have to show reliability in the joining of steel plates from a half-inch to one inch in thickness. To this and kindred problems the committee immediately turned its attention.

The work had all been done in the field where it had been applied by practical men. It was first necessary to formulate the proper nomenclature and symbols. This was thoroughly investigated and a very comprehensive set of symbols has been approved by the committee and is in daily use by those now actively engaged in this new application. The approved nomenclature introduces the subject to the designing and calculating engineer and gives him the instrument by means of which he is able to place his thoughts rapidly and conveniently on drawings.

The manufacturers of apparatus joined the practical man in the study of the problems of electric welding. Apparatus and so-called processes introduced various types of machines suitable for the conversion of electrical supply to the proper values of current and voltage needed at the arc or at the spot. The manufacturer in his eagerness to meet the problem naturally encountered many difficulties. These difficulties increased until a point was reached as referred to above where he demanded some standards upon which his apparatus could clearly be rated. Therefore, the manufacturer was only too pleased to co-operate with the Welding Committee and is to-day conscientiously aiding in straightening out the difficulties in which he was involved prior to last year.

Arc welding in this country has largely been done in the railroad repair shops. It was discovered that the process was much cheaper and could be performed more rapidly than by any of the gas welding methods. It also could be applied without preheating and in many cases without the expense of disassembling complicated pieces of machinery. Spot welding besides being used in many different industries was sought for by the railroad man and there has been built a gondola car which has seen some seven or eight years of service. It is interesting to note here the difference in practice between Great Britain and the United States. The former knowing little or nothing about spot welding had the practice and application of arc welding very well under way; the latter exactly the reverse.

Apparently the attempts to train operators were rather crude and it was early observed that the reliability of the electric weld depended substantially upon the skill of the welder. The manufacturers of apparatus and the superintendents in railways shops had struggled with the problem of training operators, but intensive study had not been given the subject so that there existed in this respect a great deal of groping in the dark.

Present Status of Electric Welding

Investigations were immediately undertaken to answer the question whether spot welding could be successfully accomplished using one-inch thick steel plates. An experimental apparatus of large size was erected and put into operation, the results showing that no difficulty was encountered with half-inch and three-quarter-inch plates. The same remark applies to one-inch steel plates. In fact, this experimental machine was successful in welding three thicknesses welds of half-inch ship structural steel exceeds the requirements of merchant ship construction. This operation has its historical significance in that this was the first time that any spot welding of this magnitude had been performed. The successful outcome of these experiments has led to the design and construction of large spot welders to be used in the fabrication of ship sections. The practical application of a large five-foot spot welder will be made at a demonstration of a forty-foot section of a standard 9600-ton ship to be built at the plant of the Federal Shipbuilding Company, Kearney, New Jersey. This is the largest portable spot welder ever built. It will prove two points in ship construction by the electric method, namely, the clamping of the ship's structural parts for assembly thereby reducing the time in working the material as well as for the erection of the ship material; and, secondly, by the speed of spot welding it will prove the decrease in time for joining the material together. The consensus of opinion is that the large stationary spot welder of five or six-foot gap will undoubtedly play an important part in increasing the speed of fabricating sections of standard steel vessels. Further investigations are being made and designs are being worked out for special spot welders for use in the construction of bulkheads. The designs proposed are chiefly for shop processes, but it can be asserted that such apparatus will be of undoubted value in the saving of time and man power.

Arc welding had been tried in a great variety of work, but there was no conclusive evidence that it could be developed to the stage of joining ship plates with the certainty of full strength. The first stage of his investigational work is now almost completed. Sample welds of half inch ship structural steel were taken by a special sub-committee to fourteen or fifteen different places where electric welding was done, noted the conditions of current, voltage, electrode, operator, etc., and then prepared the welded samples for tests. The samples were forwarded to the Bureau of Standards in Washington so that the tests should be conducted by parties absolutely disinterested and without knowledge of how the samples were obtained. The results of these tests showed a remarkable similarity especially when it is realized that they were made by several firms with different electrode materials and under varying conditions of the electrical current. Practically all of the welds pulled at over 50,000 pounds per square inch and several over 60,000 pounds, the average being about 58,000. On the bending test one of the samples was bent to an angle of 78 degrees before a crack started and final failure reached 80 degrees. In another case the sample was bent to 65 degrees before the crack started and final failure did not occur until 86 degrees. The point of importance here is that all the welds showed a reliability and satisfactoriness which makes conclusive the opinion that electric arc welding is applicable for the joining of steel where the structure is submitted to live loads, bending strains, static pressure, or the like.

To give a further indication of the large size practical tests which are being carried on at the present time it may be stated that three 12-foot cube electrically welded tanks are now being constructed. These tanks are built in such a way that from twelve to fifteen different designs of joints are used in their construction. After these tanks are built they will be subjected to a static strain and the deflection of the seams will be directly measured. Afterwards they will be tested by external shock and crushed to destruction. Portions of the joints will be cut, sent to the Bureau of Standards, and again tested for the sake of accumulating precise data. In this connection there is being built at the Norfolk Navy Yard a battle-towing target. The keel of the target 110 feet long will be entirely electrically welded and the results of this practical demonstration will be carefully recorded after it has been put in regular service.

Alternating Current Found Advantageous

It is to be expected that the manufacturers of apparatus being keenly observant of the increased interest in electric welding as well as in the future, which is probably now unquestioned, would be active in their desire not only to improve their present facilities and their design of apparatus, but also to proceed themselves to follow the trend of the investigations made by the Welding Committee. The consequence of this has been a large increase in output of apparatus that is needed. One interesting point is that certain manufacturers who were decidedly of the opinion that direct current was the only proper current to use for arc welding have within a very recent period changed their point of view and are willing to admit that alternating current may have certain advantages in the development of this art.

The electric arc requires a reduced voltage and this is difficult to attain with direct current without relatively expensive machines or a useless expenditure of energy. The practice in this country in manufacturing establishments of any size has been toward an increase in the supply voltage so that very few large manufacturing plants use less than 220 volts direct current. With this voltage the only economical method of transformation is in the use of a motor-generator set. The efficiency in this case is in the neighborhood of 50 to 60 per cent. It is possible to use a supply voltage of 110 volts with a variable resistance which cuts down the voltage to the arc volts. This gives a very poor efficiency. In the case of alternating current the supply voltage can be reduced by a transformer which will supply as in the case of direct current a sufficient voltage for striking the arc and a satisfactory reduction when the arc has been struck. On the other hand, if a low voltage alternating current is provided a simple reactance may be introduced which has some of the same wasteful characteristics of the resistance used with the direct current. The average apparatus will permit of electric arc welding consuming about six to eight kilowatts per welder, but if low voltage is provided there are certain outfits which will reduce the consumption as low as three and one-half kilowatts per welder, or even less.

Without entering into an elaborate analysis of the relative cost of electric welding, it may be broadly stated that there is hardly any question that the electric process is cheaper than any other. The same may be said as regards speed and also reduction of man power. In a recent discussion of this subject President Adams stated that at one of the Eastern shipyards the total number of parts on the welding program of the standard riveted ships now building at that yard amounted to 225,000. The labor cost for riveting these pieces is about $245,000 and for welding about $99,000, making a saving of $146,000. But this is only a drop in the bucket when compared to what might be profitably done in this line. He stated further that in certain particular instances the saving is as great as 90 per cent.

One of the interesting questions discussed with some fervor by the members of the Welding Committee is the advantages of the bare and covered electrode. Regarding this discussion no definite facts can be stated. In England the practice has been to use the covered electrode which protects the welding arc from contact with the air thus guarding against too great a formation of oxide. The practice in the United States up to the present time has been largely bare wire. Recently, American investigators have discovered the important fact that there are advantages in the covered electrode and many experiments are now being made, some with results. It is important to observe that in the above mentioned tests of welds, the best one of these samples was made with a coated (not an abestos covered) electrode using alternating current. The point in this case seems to rest upon the question of the dutility of the weld and it would seem that the bare electrode does not make as ductile a weld or at least one as easily bent as the coated or covered electrode. The question of the ductility of the weld is one of much importance in the application to ship construction and will doubtless be of importance to other allied industries. It is, therefore, a question of serious importance and constitutes an important part of the work of the Sub-committee on Research.

No matter what the type of electrode is nor its composition, no matter what kind of shank material is to be welded, no matter what kind of apparatus is employed, the reliability of the weld rests mainly upon the man who welds it. This man if he has been properly trained and is skilled in the art knows instantly whether he is making a weld or not. He becomes after much practice able to judge fairly well upon looking on a finished weld whether it is a good weld or not. The work of training electric welding operators early became a part of the functions of the Education and Training Section of the Emergency Fleet Corporation. The men connected with this work are members of the Welding Committee. Schools for the training of operators as well as for the conversion of operators into instructors, are established in many parts of the country. The objects held in view by the training department are first to give the man intensive practice work so that he becomes a good craftsman. The methods are simple to start with, as the exercise of the right arm muscles must become flexible enough to permit the operator to give the required movement to the electrode. By a graduated series of exercises this is accomplished in about eight weeks. The man is allowed to do production jobs in the shop which gives him confidence through responsibility. It becomes desirable at this time to give the man some outside work on ships and where this is practicable it is done. The man is then turned over to an instructor who gives him an intensive course in pedagogics lasting from five to six weeks. At first sight it would not seem necessary to instruct a man, but it is not generally understood that teaching after all is itself a trade. The experience with the men in this respect is most interesting. In nearly every case the man has resented this course at the start, but at the end has turned completely around and in many cases has desired an even more extensive training. What is really accomplished is to give the man the necessary confidence to impart the knowledge that he has gained to another green man. The men under training are taken from the various industries, especially the shipbuilding industry, and after they have finished their instructor course are returned to their employer to carry on the instruction, in their own plant. The men who go through this training as provided by the Emergency Fleet Corporation are certificated when they have shown themselves to be entirely proficient. It is not possible nor expedient for the Emergency Fleet Corporation to require the certification of all electric welders. It is the consensus of opinion that all industries doing serious work with the electric arc should use men who are ceritfied as to their ability in the art of electric welding. The main reason for this opinion is that the operator must be a conscientious workman or the weld will not be of perfect quality.

This brings forward another problem upon which a great deal of experimental work has been and probably will continue to be done, namely, a practical and scientific method of testing a welded joint that has been made. There have been a number of suggestions made for the solution of this problem. They are briefly, as follows:

(a) Mechanical. By hammering the weld or by chipping at frequent intervals.

(b) Electric. By means of resistance or voltage drop.

(c) Magnetic. By means of the permeometer or the change of conditions of the magnetic circuit.

(d) X-ray. By means of an exposure on an X-ray plate.

At the present time none of these suggested methods have been productive of conclusive results and recourse must be had to the purely mechanical methods of striking heavy blows on, or adjacent to, the weld or by using a chipping hammer and making intermittent examinations. It would seem by far the best procedure to make the inspector proficient in the art so that he may closely observe the welders while at work. This may be accomplished by a two or three weeks' attendance of inspectors at any one of the electric welding training centers.

Methods of Electric Welding

There are many methods and processes of electric welding but the two main ones that interest the committee at the present time and alone have been mentioned so far are the spot welding and arc welding. It may be a surprise to some of the old time welders to consider electric welding as a new industry. In substantiation of this statement it may be well to describe briefly what is meant by electric welding as it is practised to-day.

Spot welding is not much different in the methods of procedure or in design of apparatus than when it was first introduced. Copper electrodes, water-cooled in the heaviest machines, are placed on opposite sides of the material to be welded together. The joint is a lap joint. Machines are now so designed that two spot welds may be made at one time. The routine of the operation is as follows:

The electrodes are brought into contact with the materials to be joined, current is supplied sufficient to give the required heat, pressure is then applied, the current is removed, and the pressure is removed, the weld is then complete.

The operator has a perfect indication of making a good spot weld by the use of a button placed under the electrode, observing which he knows exactly the proper timing of the operation. There is, therefore, no question as to a good, bad, or indifferent, spot weld. Automatic spot welders have been designed and built, but it is the general opinion that they add complication to a process which in itself is very simple.

The process of arc welding is as follows:

One side of the electric circuit is connected to the material to be welded; the shank material is usually prepared by bevelling the edge of the pieces to be welded together. The other side of the electric circuit is connected to the electrode. By touching the electrode to the shank material the arc is drawn. The skilled operator now moves the electrode from side to side of the groove giving a semi-circular motion while at the same time moving the electrode along the groove.

It is important that the arc "bite" into the shank metal creating a perfect fusion along the edges and the movement of the electrode is necessary for the removal of any mechanical impurities that may be deposited. In the coated electrode it is further necessary that the slag which forms for the protection of the pure metal be worked up to the surface and it is extremely important in the event of a second or third layer that the slag or impurities be carefully scraped away before the virgin metal is again laid on.

The operator in arc welding is protected with either a hand screen covering his face with special glass through which to observe his work. The electric arc emits dangerous invisible rays in both the upper and lower spectrum scale and it is quite evident that both the infrared and ultra-violent are dangerous in their effect, the former is pathological, the latter actinic. The operator further uses gloves for his hands and for the very difficult work of overhead welding it is necessary for him to use a helmet which partly covers his breast.

The tendency of developments in spot welding has already been slightly touched upon. In their nature as applicable to shipbuilding the advancement will naturally have to proceed toward means for accomplishing spot welding in very cramped locations. This makes an exceedingly difficult problem as the power requirements are such as to preclude any very small device. In riveting one-half of the apparatus is on one side of the work and the other half on the opposite side and it is difficult to conceive of any method of spot welding that will admit of such an arrangement. In shipbuilding it is quite probable that designs may be made that will permit of a large or at least increased amount of spot welding in the actual construction of the vessel. Certainly, present designs of riveted ships will not allow of this to any great extent. As already stated, spot welding can now take its place in the fabricating shops and it is to be expected that within a few months spot welding will begin to supplant riveting in this field. The only drawback to this will be the sufficient production of spot welding apparatus.

The tendency of development in arc welding is toward the automatic machine to obviate the responsibility that has to be placed upon the skilled operator. Intensive work has been done within the last few months in the line of automatic arc welding machines and at the present time sample tests of welds made by such apparatus have been sent to the Bureau of Standards. These machines will occupy a very important position in repetition work. They will not immediately supersede the skilled operator in repair work, or in special jobs but it may be expected that the development of such machines will bring apparatus which can be man-handled and will eventually take the place of most of the hand work as it is now known.

Of the scientific advancement in the art of electric welding there is so much to be treated that only a general outline can be considered at this time. The research work has only just begun. Practice has preceded the scientific investigation. The field, therefore, is full of most interesting problems. Those who have been following the development of the past six months are deeply interested to know the fundamental reasons. The investigational questions may be grouped into three main divisions:

1. Metallurgical; 2. Physical; 3. Electrical.

The metallurgist has yet to tell us what the conditions of the metals are after the electrode material has fused with the parent metal, and to determine what the proper conditions must be to produce a good weld. This problem has in it a great many variables. The physicist must explain the atomic or electronic conditions which permit of the combinations at the high temperatures involved and must explain the phenomenon of overhead welding. The electrical investigator must determine all the various phenomena connected with the preferences between and the advantages of the use of different forms of electrical energy and the varying characteristics of the electric circuit in producing different type of welds.

Conclusions

From the preceding remarks it must be conceded that the Welding Committee of the Emergency Fleet Corporation has already crystalized the problems connected with this art. The working functions of this committee have been laid down upon the broadest possible lines. Liberal opportunity has been given every one to state in detail his opinion and to express the reasons for his preference on every point connected with this subject. The committee goes even further than this. It furnishes those interested with every new idea that is brought to bear upon the subject after sifting from the suggestions any question of doubt or misstatement of fact.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

THREAD ROLLING IN A SCREW MACHINE

By M. H. POTTER

The rolling of threads by hardened rolls, or dies having threads which roll grooves into the blank and raise enough material above the surface of the blank to form a thread, has been in use some time, especially when a thread is required next to a shoulder where it would be impossible to cut with a die. The tool used when threads are rolled in an automatic screw machine is in the form of a disk, having a thread periphery and mounted so as to revolve freely when forced against the blank to be threaded, the thread on the roll or tool being the opposite hand to the one which is to be produced on the work. For rolling a right-hand thread, the work should revolve in the same direction as when a thread is cut in a lathe. The roll-holder should be provided with vertical adjustment, so that it can be set to the correct height.

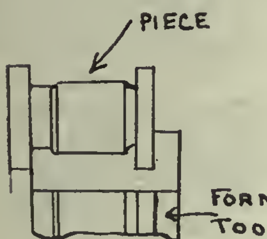

FIG. 1

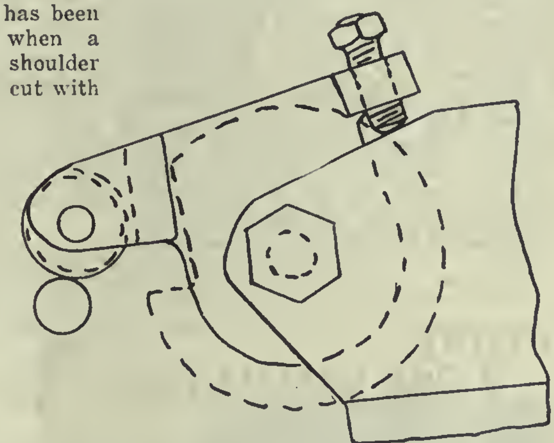

FIG. 2

Due to the difficulty in securing material for the rolls that will withstand the severe use of rolling threads in harder metals, thread rolling is only practical when applied to brass or other soft metals. It is possible, however, to apply this method of producing threads in steel when chrome-nickel steel rolls are used.

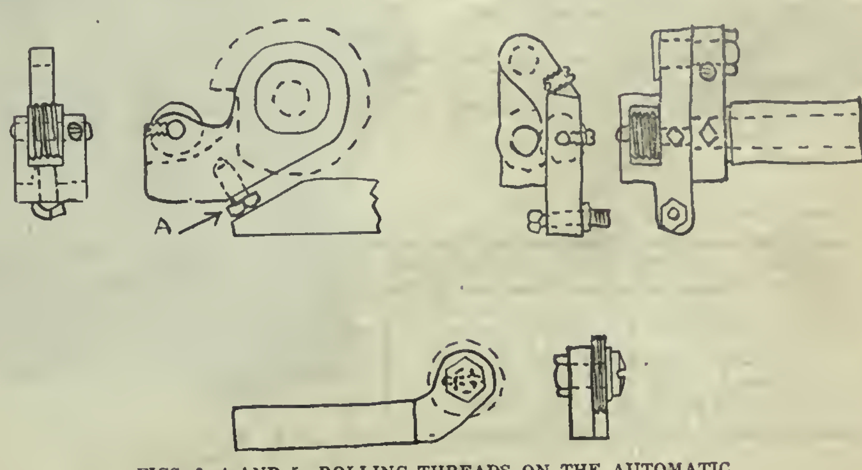
The diameter of the blank should be approximately equal to the pitch diameter. In the case of a U. S. standard thread, the diameter of the blank should be slightly less than the pitch diameter of the thread. The threads on the roll should be made sharp at the top, otherwise more pressure will be required to force the roll into the work, which will produce a rough, imperfect thread. In other words, all thread rolls, whether for forming a sharp V or a U. S. standard thread, are made with a sharp V at the bottom. As the outside diameter of the thread formed is governed by the diameter of the blank, there would be no advantage in having the bottom of the thread on the roll sharp, with the exception that it would be easier to machine the thread in the roll.

In making a thread roll, the outside diameter is turned to the size required, and the end beveled at 45 degrees to prevent the end thread from breaking out. The roll should be lapped after hardening in order to obtain a smooth finish on the threads. This is accomplished in the usual manner of lapping by means of a piece of hard wood charged with fine abrasive and oil, while the rol is rotated on an arbor.

As the part of the work on which the thread is to be rolled can be turned by a form tool, it is preferable to use a form tool of such a shape that it will cut a groove at the end of the thread to be rolled, i.e., the end next to the shoulder. This is illustrated in Fig. 1. It is also desirable to reduce the diameter where the work is to be cut off from the bar stock; this is also shown in Fig. 1.

Naturally, the method of holding and applying the roll is governed by the relation that the thread rolling operation bears to other machining operation on the piece. The design of holder for the thread roll is also governed by the type of screw machine for which the holder is intended.

The holder shown in Fig. 2 is attached to the cross-slide and operates tangentially on the top side of the work. The one referred to was used on a Brown & Sharpe machine. There are no chips to interfere with the operation and the roll can be held more rigidly than by passing it under the work. This is due to the fact that the tendency is to raise the cross-slide instead of to push it downward. As will be seen by referring to Fig. 2, the roll rotates on a pin and is inserted in a slot milled in the end of the holder. The roll should be a good running fit, both on the pin and in the slot, as any lost motion would result in a marred thread. The



FIGS. 3, 4 AND 5—ROLLING THREADS ON THE AUTOMATIC set screw shown at the rear of the holder is used for setting the roll to the proper depth. In this instance, the cutting-off tool was located back of the thread doll so that the work will be severed from the bar before the roll returns. The roll should be moved in to about .010 inch from the work on the quick rise of the cam, and then be fed in until the roll is directly over the top of the work. The feed should be about .002 to .004 inch per revolution of the work. The roll then moves past the work rapidly, bringing the cutting-off tool into position.

The thread roll holder shown in Fig. 3 is attached to the cross slide, and the roll is so located that it passes beneath the work when forming a thread. The set screw A bears against the cross-slide and is used for adjusting the roll to the proper depth as well as for supporting the holder. This type of holder may be used when no other tool is operating on the work at the same time and there are no chips to interfere with the thread rolling operation. The cutting-off tool located back of the roll severs the work after the thread is finished, so that the roll does not come into contact with the thread on its return movement.

When the thread roll cannot be carried on the cross-slide of the machine, a swing tool of the design shown in Fig. 4 may be used. If it were necessary to feed in the cut-off or form tool more than once on the same piece, a swing holder should be used. This holder operates upon the same principle as an ordinary swing tool for turning. The swing arm which carries the roll and which is moved inward, for bringing the roll into contact with the work, by means of a raising plate attached to the cross-slide which engages the set screw located at the end of the swinging arm. The shank of the holder is inserted in a hole in the turret. If the length of the work exceeds about 2½ times its diameter, the swing-roll holder should be equipped with a support. A hole drilled through the shank of the holder and a set screw is provided for holding the supporting member. The method of applying this support is governed by the shape of the work.

A type of thread-roll holder commonly used on multiple-spindle automatics is shown in Fig. 5. The thread roll is fed in radically to the work and slightly off center, so as to permit the tool to swing away a certain amount to follow the curvature of the stock. This makes it unnecessary to set the tool absolutely correct in regard to position for depth of thread. The spring of the tool should not be excessive, but just enough to relieve the strain which would be imposed on the tool if it were in a central position.

FORM FOR MAKING MACHINE COST ESTIMATES

WHILE it mav be that there is nothing particularly new about the estimate form shown in Fig. 1. its use does not appear to be general in some shops. The large concerns usually have estimate forms which save time and work, but the little fellows do not generallv seem to appreciate the value of "tools" of this character. In a small shop where there are not many estimates to be made the form shown can be drawn in ink on tracing cloth and a brown-print negative made from the tracing. Then, to obtain white, blank forms, upon which estimates can be compiled, blue-line white prints may be made from this negative. Where the number of estimates made is large, the form should, of course, in order to insure maximum economy, be printed.

As to size, it is convenient to have the form reproduced on 8½ by 11 inch sheets—the standard size letter sheet—so that the estimates may be filed with other correspondence and in the job envelopes without folding. For certain classes of work, however, an 8½ by 11 inch sheet may not be large enough, in which case the size of the sheet can be about 12 by 16 inches.

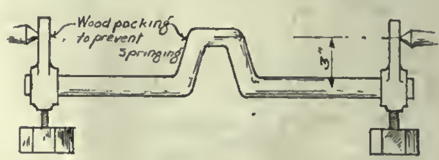
The feature of the form which renders its use desirable is that the principal component costs—some of which may, if they are not carefully listed, be overlooked—are all set down in black and white on the form so that the possibility of omitting some cost item in making the estimate is reduced to a minimum. It may be desirable for certain lines of work to include cost items, other than those shown in Fig. 1, on the form.

As will be noted, the first columns give an estimating description of each piece, the number of pieces required; the kind of metal in the column headed "of," the weight of the piece, the price per piece and the total cost of the number of pieces of each kind. The columns headed "price" and "cost" are not filled out until the pattern cost, machinist cost and the blacksmith cost detailed in the three main columns to the right have been compiled. This form has been used for a number of years, substantially as indicated in Fig. 1, and has been found wholly adequate. —G. L. Waters.

TURNING THROW OF SMALL CRANK SHAFTS IN CASES OF EMERGENCY.

By J. J. DIXON.

In the ordinary way of turning the throw of crank shafts it is necessary to have two quadrants to get the required distance of centres from body of shafts. To make these takes up considerable time and often costs more than the operation of turning the crank and are not required again for a considerable time. This expense and time can be saved by adopting the following wethods:—Take two ordinary lathe dogs, which will take in the size of the body of shaft, lay the shaft on marking-off table, put the dogs on each end, line them up with surface gauge, strike the centre line with body of shaft, then with compass strike the required distance of throw, drill centres in dogs where lines intersect. This must be done while dogs are in position, care being taken that dogs are well tightened down on shaft—a careful lathe hand will have no difficulty in turning a crank throw by this method, the writer having done this with cranks up to a 4-inch throw.



METHOD OF TURNING CRANK

Portable electric machinery has been invented to screen coal and load it in wagons.

FORM FOR COST ESTIMATES

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

DANIELS AUTOMATIC MACHINE

WITH the object of providing an easily operated automatic machine for making a variety of machine parts, only semi-skilled labor being employed, the machine shown in the accompanying illustration was recently developed. It is the invention of Lee G. Daniels and David Sundstrand, both of Rockford, Ill., and is being manufactured by the McDonough Mfg. Co., Eau Claire, Wis. In principle, the machine resembles the modern manufacturing automatic of the type having several working stations and one loading station. As the illustration shows, the machine is of the vertical type, the object of this design being to facilitate loading and unloading.

The machine handles work from 2 to 6 inches in diameter and performs the following operations: Cup turning, drilling, boring, reaming, facing, tapping with collapsible taps and drilling multiple offset holes by means of an attached multiple-spindle auxiliary head to any of the spindles.

The machine has five tool carrying spindles and a blank station. The turret, upon which the spindles are mounted, does not revolve but through its automatically controlled vertical movement, feeds the tools to the work. Its axis is concentric with that of the table.

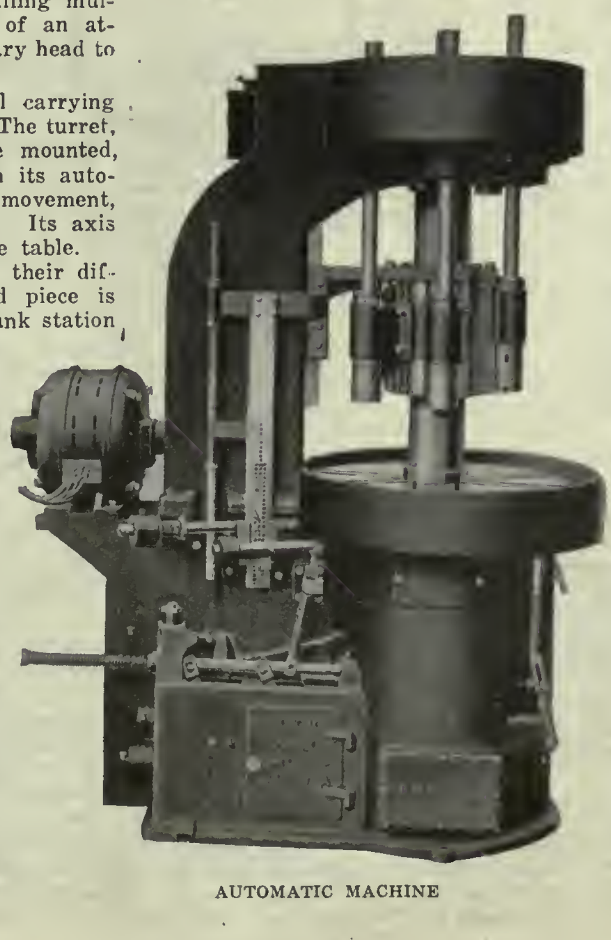
After the spindles perform their different operations, a finished piece is removed when it is at the blank station and another substitued. The time of machining a given piece is the time of the longest operation plus the time of one index.

The table has six chucking positions and revolves step by step, bringing each chucking position successively in alignment with each spindle.

On one machine now in operation, machined pieces are turned out, it is said, at the rate of one every two minutes. Three machines which were previously required for machining the parts, have been eliminated and three operators released for other work.

The spindles have a rapid approach toward, and a rapid reverse from the work. The spindle carrier is operated by means of a quadruple screw operating through a bronze nut in the center column. The screw is revolved by means of a worm gear and the worm by means of three friction clutches, one for a rapid approach, one for the feed and one for a rapid reverse. In obtaining these movements through friction clutches, the machine is protected because if a tool should break and jam in the work, the feed pressure would go up and cause the feed friction to slip, thus automatically protecting the machine. If in the movements of the rapid approach or reverse or indexing of the table, any of these should jam into anything, their friction clutches would slip.

The table is 36 inches in diameter, and can accommodate six 10 inch chucks or work holders. The travel of the spindle carrier is 13 inches, and it takes 4 inches of this movement to withdraw the locating pin and to control the indexing of the table. The table can be set to index one, two or three spaces, depending upon the operations required.



AUTOMATIC MACHINE

The speeds are varied by means of change gears. There is one set that controls the speed of all the spindles and each spindle also has an individual set of change gears, so that each can be given the most efficient speed for any particular operation.

NEW DESIGN OF BORING MACHINE

By J. H. RODGERS.

Difficulties contingent to the boring of the heavier shells has been one of the greatest problems of munitions manufacture. Owing to the length of the bore the cutting tool required to be at a correspondingly greater distance from its fixed support in the turret or carriage. This not only meant that the cutter bar must be made as heavy as conditions would permit, but the slides and other movable parts of the carriage should be as close a fit as possible consistent with effective operation. Various tools have been designed for this work and many have attained a high degree of efficiency, virtually revolutionizing the operation of shell boring. Overcoming the leverage created by the excessive overhang of the tool has been the general object of the various designs, but few have entirely eliminated this weakness. Heavy and large diameter turrets, increased bearings given to carriage ways, tail pieces extending back to the lathe shears, and other methods, have been adopted, but although they assisted to maintain the accuracy of the work the fault still remained in a modified form.

The machine here illustrated has been designed and constructed by L. A. Desy, consulting engineer of Montreal, and incorporates some interesting features of construction. In proportion to its capacity, the machine is relatively light in weight, but the construction is such as to maintain the initial accuracy and rigidity under long and continued service. The general appearance of the machine differs little from that of other boring tools, with the exception of the arm and the support for the cutting tool bar and forming point; but these portions of the machine vary considerably from the usual design, inasmuch as the troublesome leverage has been amply taken care of, the tool being provided with both horizontal and vertical support, forming what might be termed a three-point radial bearing. Of course, the spring of the boring bar still remains, but with the bar made of ample size the trouble from this source is very slight.

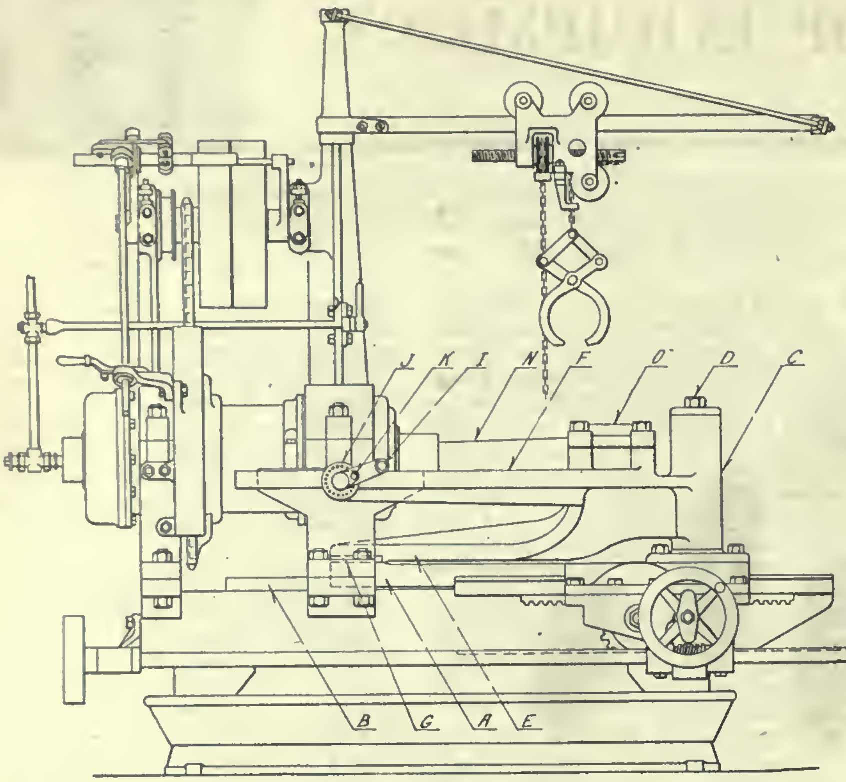


FIG. 1

As shown in the assembly view, the carriage is provided with a heavy arm A that extends forward and beneath the front head stock bearing, this being of the bridged type. A groove of ample width and depth is made in the lower outer end of this arm that fits closely on the tongue slide B. The carriage is provided with a pivot D upon which the main casting C is fulcrumed. The lower section of this casting forms an arm E that extends forward and under the headstock, the extreme end being machined to slide freely on the upper surface of the carriage arm A. The saddle arm has no side movement, but the upper one is made flat to allow of side motion for setting the tool and shaping the desired profile. The horizontal arm F extending out to the front of the machine, carries at its extreme end the forming point H, which is in a direct line with the cutting tool.

A feature of the adjustment is the method of determining the setting of the tool for the removal of metal. The adjusting screw is provided with an integral collar J containing a series of 25 equidistant spaced holes. The small crank arm is fitted with a spring pin K that enters one of these holes and locks the two parts together. The outer end of the small crank arm carries the handle and stop pin I. The pitch of the adjusting screw is 1-16 inch and the disc contains 25 holes, so that the adjustment between two adjacent holes would be 1-400 inch, or a difference on the diameter of about 5-1000 inch. The sizing and profiling cam L is secured to a support M on the front head stock and is capable of close and accurate alignment.

The spindle chuck is so constructed that a positive grip is provided at each end of the shell. The air operated cylinder B is fitted to the rear of the spindle in the usual manner and is provided with a small feed pulley C, the air connection D being of special design with the air inlet in the middle. The push casting F is secured to the piston by means of bolt G, this bolt serving in a double capacity, the front end supporting the ejector H operated by the spring I. The rear collet J is operated direct by this push casting, and by means of the body bushing K, the front collet L is operated, the screws M preventing the jaws from side movement. Six springs N, bearing against the piston and the ring O, return the piston to its released position,

This action is assisted by a series of small springs P, placed between the push casting F and the body bush K. These machines are being manufactured by The J. W. Harris Manufacturing Co., of Montreal.

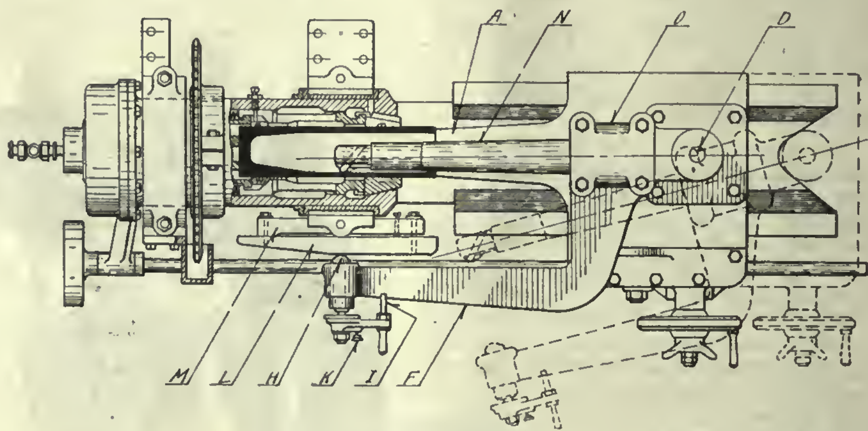

FIG. 2

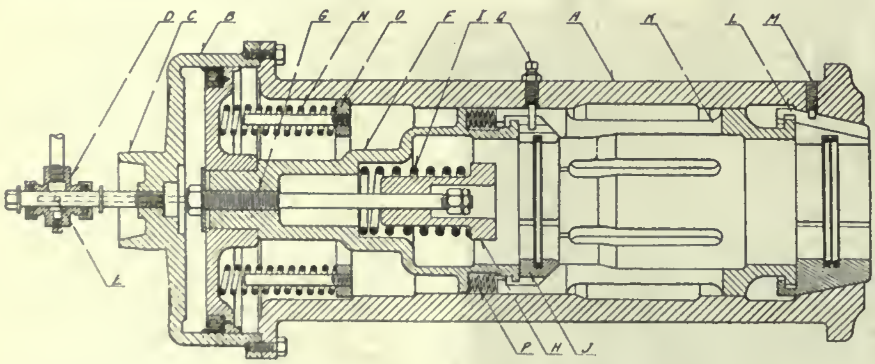

FIG. 3

Owen Sound.—The Corbet Foundry & Machine Co., Limited, Owen Sound, are building six automatic towing machines, of their No. 5, or longest type, to be installed in six ocean-going tugs now being built at Buffalo. Mine sweeping attachments, consisting of gears, shafting, and drums are included in the specifications. Each towing machine will be equipped with 1,800 feet of 2-inch hawser. The tugs are being built for the U.S. naval service and are to be employed in mine sweeping and other lines of ocean duty. The Corbet plant is employed on much other work for ships now building in yards from Halifax to Vancouver.

Technical Journal Best Aid to Education

Stationary Engineering Becoming Highly Technical and Specialized Avocation With Increasing Prestige—The Technical Press is Recognized as the Best Means For Procuring Advancement Through Increased Knowledge

By S. BALMFIRTH, Engineer Sick Children's Hospital

IN these days of war, of coal shortage, and rumors of further shortage, the engineer is being called upon for increased efficiency as never before.

Coal, which two years ago was plentiful and fairly cheap, is now scarce, poor in quality (frequently) and high in price.

These conditions have resulted in a demand from manufacturers and governments for a more efficient and economical system of power generation. That is to say both manufacturers and governments are putting the question right up to the engineer as being the man most likely to produce the results required.

However the work of a steam engineer is not learned in a day, but is a long, tedious and very often painful process. The engineer, unlike most of the manual tradesmen, is never out of his apprenticeship. He is like a man rowing a boat upstream; if he stops rowing he drifts back. So it becomes every engineer worthy of the name to keep everlastingly at it. In fact in these days of progress and invention in every line of business, it is absolutely necessary that one devote a fair amount of time to learning the finer points of one's chosen line. Nowadays the up-to-date chief engineer is being classed, at least as a semi-professional man, which is only right for certainly steam engineering has got past the old rule-of-thumb days.

Time was when the fireman of to-day was the engineer of to-morrow. That is, the beginner in the steam engineering profession began as a fireman, and from the experience he got as such, and from his observation of what the engineer did and from what the engineer was willing to show him, he progressed slowly and laboriously until he had sufficient knowledge (or thought he had) to apply for a position as engineer. If he succeeded in getting a position as engineer, his troubles began. Then he found quite frequently that engineering was "not just what it's cracked up to be!" However, if he succeeded in keeping the wheels turning without having to call in outside help, in most cases he would be able to hold down the job long enough for him to learn more about his business.

Of recent years, however, in keeping with the general progress of education the engineer is fast coming into his own.

No longer is he known as "the man in greasy overalls carrying a monkey wrench," although both these articles are very necessary adjuncts, but he is being recognized as a very necessary and important man in any business, by the most prominent manufacturers.

It is not necessary for any engineer to depend entirely upon his own experience for his information. Nowadays there are books published for self education (some of which are suitable and some are not), correspondence schools, free libraries, night schools, engineers' associations and many other ways open to the seeker after knowledge.

The writer has used most of them, with varying success. Experience is, no doubt, the best teacher, but her course is very expensive. So it is very much less costly to use the other fellow's experience.

Any one can profit by his own mistakes, but it takes a wise man to profit by the mistakes of others. Of the sources of information mentioned above each has its good points, and each its disadvantages.

One of the disadvantages of the technical book, is generally speaking, it is not written for self education. It may be intended for that purpose, but very frequently falls far short of fulfilling its purpose. Many of them are couched in language entirely beyond the average engineer's education, and require a teacher to explain. Further, the best book written at once grows old and out of date the moment it is published.

Correspondence schools fill a great want in this regard, in that their text books are generally written for self instruction. Most of them are written in simple language, and carry the student along step by step from the first rudiments of the subject in hand to its final conclusion. Further the correspondence school saves the time required in travelling to and from home and school, and also makes use of any odd minutes that the student may have to spare. The writer put in a good many hours' study on the street cars.

Technical schools, that is evening classes, are an excellent means of providing higher technical education for the man who can attend. But right there is also the disadvantage. No course of lectures will benefit a man unless he can attend all, or at least the largest proportion of them, and the average plant engineer cannot be certain of being able to attend all lectures. Things have a habit of going wrong on class night, and one of the most important lectures is missed, and then the whole course is thrown up in disgust. Then again many engineers cannot attend by reason of the time of their watch, so that they have to forego the benefits of the night class.

Still for those who can attend the night technical school is an ideal means of acquiring an education; combining as it does the use of spare time with both practical and theoretical courses of study.

The engineers' association is a very good means of self improvement; in fact one of the best. If the association is at all alive, discussion of various subjects of interest to all engineers is the main part of the evening's business. Every one has a chance to express his opinion, and many and various are the opinions expressed at times. Still, by discussion one learns, and by friction a polish is given. So that even if one makes mistakes in giving expression to one's opinion, it is not often that one makes the same mistake twice. Then again a mistake made in discussion of any subject is much more easily rectified than a mistake made on the job; it is not likely to be so costly either. The older engineers are always ready to help the younger ones, by giving them the benefit of their experience.

But!——— if you wish to learn about any subject, write about it. One could safely say that what one writes about, one remembers best. Not only that, but what one writes about one generally takes care to be accurate.

So, the technical magazine has a field all its own. In it one can express one's opinion on any subject covered by the magazine. Not only that, but the criticism evoked is often constructive, in fact generally so. Further one can ask any question and be sure of geting an answer. There is generally someone who knows the answer to the question and is willing to pass the information along.

The technical magazine has one great point in its favor, that is, it is never out of date. One can always be sure of finding the latest improvements and the newest inventions in its pages. Then again the advertisements are a fruitful source of information of what is new and

A Big, Serious Question Ahead

THE parliamentary secretary of the Department of Civil Re-establishment has resigned. This is not the time for men in that kind of work to be quitting the job.

If conditions were such that he could not work to advantage, then put conditions right.

The war wound up with such a rush that the government was not prepared for it. That, at least, is the most plausible excuse that can be put up. But just now people are not strong on accepting excuses.

The responsibility of the government toward the industrial life of the country does not end with the signing of an armistice. The government, through conscription and its War Trade Board, and the operation of the Imperial Munitions Board, created the war machine. Having created it by turning the industrial life of the country up on edge, the duty now is to restore it to something like normal conditions.

It must be remembered that manufacturers in Canada were denied access to the steel markets, to the pig iron markets. Canadian industry has been at the beck and call—and willingly so—of the Canadian war machine.

And now what? The government cannot say, "The war is won, and we're through." No department dare drift until the resignations of able members are necessary.

"One Thousand Hands Laid Off At Shell Plant." That's bad business, and it's dangerous business as well.

These one thousand have made good money. They have needed good money to pay 15 cents a quart for milk and seven cents each for eggs.

Turning thousands of men into an unprepared labor market, with the price of food still at the peak, is simply harrowing and plowing and sowing the seed that springs up into Bolshevik ideals and mob excesses.

If ever there was a time in the history of Canada when the country had a right to look to Ottawa for sane deliberation and fearless action, that hour has struck.

The body that had to do with war contractors, viz., the Imperial Munitions Board, will cease to exist in a few days. To whom, then, are the manufacturers to turn if they want a hand at getting back to old lines that have been sacrificed or neglected in the rush for maximum munition production?

Canada does not stand in the place of a nation that has to deal in a niggardly way with the situation. It is better to blunder by too great efforts and consequent expenditures than to court trouble by meeting the situation with the vision of a pinhead and the courage of a slacker.

The suspicion grows that Ottawa is not in shape to cope with the situation. It may have been commendable in the days of Micawber to "wait for something to turn up," but that sort of stuff won't do to-day.

There must be the same energy in looking after the returned man that was displayed in signing him on, cheering his departure and noting the progress he was making in France.

Ottawa has a chance right now to make a big success, or a failure that can be nothing short of an awful mess.

Dealing With the Foreigner

THE Department of the Interior of United States is now issuing a little paper called "Americanization Bulletin," with the idea of working with the foreigners of that country toward the end of better citizenship.

There is a great big field here for the United States or Canada for that matter. The trouble in the past has been that the foreigner has come to this continent as a foreigner and he has lived as one. He has not become a citizen of United States or a citizen of Canada.

To be true we do pay some attention to the foreigners in this country. We send inspectors now and then to raid their houses to see if they have more than the regular schedule of liquor. We send other officials to look around their back yards and see that they are up to snuff from a sanitary standpoint. And to be true we have them rounded up in court once in a while, and through an interpreter we tell them that they must part with five and costs for living in this country the same as they have been used to living in the land of their birth and former residence.

But apart from that what do we do for the foreigner that will make him a better man for this country? The answer to all this is "Mighty little."

People in this section of the country may not see the problem in the same light as those who live in corners of the country where the foreigners have a chance to hive. In these places they dominate the situation in many ways.

If all we can do with the foreigner that comes to this country is to get him to do work that the natives won't do, then we can't expect to amount to much as a nation. It is an admission that we have no national ideals, or no scope past the pitching of the foreigner into the industrial sausage mill and making him spit out dollars.

The foreigner as he comes to us is a problem. In fact he's so big a problem that we can't afford to ignore him. From the low plane of self-preservation we will have to take notice of his presence.

The Department of the Interior of United States is working toward the right end. It's to be hoped that their efforts are not allowed to come down to the poor status of academic discussion. The Department is up against a big problem. If it solves it the country at large gains. If it does not the country is the loser to the same extent.

At a banquet in Toronto the other night the chairman announced that they would sing "God Save the King." Whereupon one husky spoke up and said, "Sing hearty, boys, there's not many of them left."

STUDY AND TRADE PAPERS LEAD TO SUCCESS

Walter A. Janssen, Operating Manager Canadian Steel Foundries, Ltd., Montreal

WALTER A. JANSSEN, operating manager, Canadian Steel Foundries, Limited, Montreal, was born in Davenport, Iowa, and received his early education at Freeport, Ill. In 1907 he graduated from the University of Wisconsin in chemical engineering. His work as draftsman and later chemist prepared him for his position of superintendent of the open hearth department and then the Steel Foundry of the Bettendorf Company, from which position he accepted that of operating manager with his present firm. Mr. Janssen is single and resides at Freeman's Hotel, Montreal.

W. A. JANSSEN

"The value of study by young mechanics," stated Mr. Janssen, "can scarcely be over-estimated, and their training is a most important factor in the success of the country's industries. Trade papers are the great clearing house and connecting link which bridges the gap existing in manufacturing circles between the office and the working force, and their educational value is conducive to greater co-operation and advancement."

At the last annual meeting of the American Foundrymen's Association, held in Milwaukee, Mr. Janssen was elected vice-president.

A 77½ Per Cent. Increase

IT'S not telling a man anything new to state that living is higher than it used to be. He knows that, and he has had it rubbed in so hard that it's almost coming through on the other side.

The U.S. Bureau of Labor Statistics has issued a book which goes into the subject pretty thoroughly. Conditions, as borne out by official figures in Canada, are much the same.

Of course there's not a heap of satisfaction in reading that your 1914 dollar has been steam rollered until it's only worth about 50 or 60 cents. But all the same it helps to answer that grand old query: "Where in Sam Hill does the money go?"

Here are a few comparisons between the first year of the war and now. The figures given represent the increased percentage of cost to the buyer:—

Sirloin steak	68
Round steak	82
Rib roast	69
Pork chops	77
Bacon	91
Ham	73
Lard	106
Hens	77
Butter	33
Milk	46
Flour	103
Corn meal	123
Potatoes	71
Sugar	65

That is an aggregate increase of 1,085 per cent. for 14 articles, or an average of 77½ per cent.

And the man who has been on a fixed salary during the war, or who has had even fairly liberal increases. finds himself still banging away with a comparative popgun at the High Cost of Living, when he needs a 14-inch shell to make a dent in the thing.

The Future of Aeronautics

HANDLEY PAGE, the maker of the famous bombing plane, has a great vision of the future of the plane in commercial business. In the *Empire Review*, he has this to say:—

"These service machines will, with some necessary internal rearrangements, make useful commercial vehicles for the conveyance of goods and passengers, the latter traveling, six or seven together, in a roomy, totally enclosed cabin. Such machines will be able to distribute the world's mails in hours where it now takes days. They will travel from country to country, and continent to continent, seeking their objectives in direct lines, ignoring the enfeebled barriers of hills and water, eliminating distances, and bringing to our shores the very outposts of our Empire. In machines of this size no part of the Old World is inaccessible, and before long the anticipated conquest of the Atlantic will bring the territories of the Americas within their reach. Trade will be facilitated and accelerated. Journeys to Africa, the East, and Australia, which are now matter for long consideration, will be undertaken by the busy man and performed at the expense of a day's time. Principal and agent will meet where they now correspond, and augmented knowledge of market requirements will result in the production of goods more readily acceptable. Planters will bring or place their samples in London and Liverpool within two or three days of plucking in India, and manufacturers will be able to grant the short time necessary to inspect their raw materials at the source."

This would mean, approximately, that a person could leave New York on Monday morning and be in London, Eng., on Wednesday morning. At the proposed six cents a mile, the cost of the trip would be over $200, quite an increase over present prices, but not a serious item to the man who wanted to cross quickly.

TECHNICAL JOURNAL BEST AID TO EDUCATION

Continued from page 655

what is standard and reliable, so that, generally speaking, the technical magazine may be made one of the best means of keeping up to date.

But to the engineer it may also be a source of revenue, besides being a general depot of information. If you have any experience that strikes you as being out of the ordinary, write to your magazine about it. If it's good enough to print, its good enough to pay for. It does not really matter if you never wrote for publication before, if the language you use is ungrammatical, or if your spelling is of an order not mentioned in "Webster's Unabridged"; send it in The magazine has men whose special job it is to clothe your idea in suitable and proper language and fit it for presentation. If you can make a sketch to help illustrate your idea, all the better. It need not be a scale drawing or an artistic piece of work; if it expresses your idea, the artists on the staff of the magazine will make a good drawing of it.

Possibly a single instance may illustrate the idea. The writer had occasion to give a paper at one association meeting, which dealt with the writer's everyday work. The writer's opinion, when he began to prepare the paper, was that he knew sufficient about the subject to make preparation unnecessary. However, as the paper progressed the writer found that his knowledge of the subject was not quite so full as he thought, so he had to consult various works of reference, but by the time the paper was ready to present the writer knew what he talked about, and in the discussion which followed the paper the writer was able to answer every question and argument. Before the preparation of the paper the writer thought he knew, afterwards he did know. Writing about a subject impresses almost indelibly on the memory.

MARKET DEVELOPMENTS

Not Anxious to Get Under the Price Drop

Inflated Values Must Come Down in Certain Lines, But No Section of the Trade Shows a Willingness to Bear the Burden—Scrap Market is Still Out of Business

MUNITIONS business in the Dominion is nearing the end. Nearly everything has been cancelled with the exception of one or two American contracts, and there seems a bit of a chance that these may stand. One is the 240-m.m. contract, a new shell with a tapered body, guns for which are now being built at American plants. This contract has not been cancelled. The making of fuses and adapters is still proceeding. In many cases shells are simply being stored near the point of production, and their ultimate disposal seems open to question.

There seems to be a disposition on the part of the trade in machine tools to dodge the day when price adjustment must come. Machine tools at the moment are about 75 per cent. in advance of normal times. It is hard to imagine that pre-war prices will prevail for some time at least, but even so, there is too much margin at present between present and old prices to encourage buying. "Let George do it" seems to size up the situation very concisely. There is also a disposition on the part of manufacturers with standard lines to hold back yet, waiting for raw material and labor to come to a lower level, knowing that the chances are that goods made now will have to be sold into a lower market by the time they have gone through the various channels of distribution.

For all practical purposes the scrap metal market does not exist at the present time. Toronto dealers admit that prices quoted are simply nominal, and only represent the comparative value when placed against the metal in ingots. They will not pay the prices quoted. That seems quite certain, neither will they name other prices because there are no deals going through on which to base the new figures. Montreal goes one better and places the figures much lower this week. The situation is not likely to improve for some time to come.

Prices of steel plate and sheets came down again during the week. There are large shipments of boiler tubes coming now, and the new lists will show a downward revision of from five to ten per cent.

There is nothing to indicate that there is going to be any sharp decline in the price of steel. In fact everything is against it. The American situation at present, on account of fully 80 per cent. of our steel being imported, finds a quick response in the Canadian situation. At U.S. points was prices for labor are still in vogue, and indications do not point to any considerable dropping in prices of finished goods.

MONTREAL HAS CUT INTO PRICES ON THE SCRAP METAL TRADE

Special to CANADIAN MACHINERY

MONTREAL, December 5.—Canada is about to start up a new epoch in her history, particularly in connection with her industrial activities. There is little doubt that munitions making will soon be a thing of the past, as recent instructions make it certain that shell production will completely cease by Christmas. It was announced some time ago that work on the British contracts would terminate on the 14th of the month, and last week word was received from Washington that the time limit on American operations would run until December 24, the date set for the final work in connection with this branch of war work. Factories in this district are now cleaning up on the machining of the shells, all primary operations having been stopped from two to three weeks ago.

Interest is centered at present in the early attitude of the government in connection with reconstruction problems. Many are anticipating a gradual return to normal activity through the present policy of the authorities at Ottawa, which, through the co-operation of the members of the War Trade Board, are hoping to secure considerable business for the rehabilitation of European countries. The removal of trade restrictions has cleared the way for a return to normal activities, but the prevailing high cost of material continues to be a factor for cautious action on the part of dealers and consumers.

Steel Still Shows Uncertainty

The steel situation in some respects might be said to have been relieved, but the general tone is still one of marked stability. Steel plates are about as hard to obtain as in the past, but the promises for the next quarter are more encouraging. It is not unlikely that the requirements will be lighter owing to the fact that the existing programme may be reduced. On the other hand many of the plants that have been working on shells are anticipating the going into marine activities, which will help to balance the stopping of munitions work. Apparently the railroads are awaiting a return to more normal conditions before starting on a buying campaign. In this respect it has been stated that the railways have been practically starved for the past three years, and replacements will be carried out as soon as conditions warrant it. It is not anticipated that any sudden decline will follow the cessation of war activities, as considerable business that has been put aside through the urgency of war requirements, is now coming forward, but the volume is restricted owing to the relatively high prices now prevailing. Despite this, however, it is not impossible that additional business will be placed even at prevailing prices. Local dealers report an unsettled situation, but a fair demand for domestic material. Some prices have declined, while advances are noted in others. The base price on iron bars, Montreal, has been reduced to $4.55 per hundred. Steel bars here are now $5.05 per hundred, a decline on the previous quotation of $4 per ton. Reinforcing bars are quoted at $4.50, a drop of $15 per ton. The reverse is shown in spring steel and band steel, the quotations being 8 cents and 5 cents respectively, the advance in the former case being 1 cent per pound, and in the latter ¼ cent per pound. This discount on cold rolled steel shafting has been changed, the present figure being 60 per cent. Black sheets, No. 10 gauge, has been reduced from $10 to $9 per hundred.

Complex Metal Situation

In common with other industrial situations, that of metals is reflecting the gradual cessation of war activities. The demand for munitions and ordnance purposes has fallen off to almost zero, but inquiries for domestic supplies have shown a slight increase, but the prevailing prices are not such as to induce consumers to buy more than they actually need for immediate requirements. Considerable interest is shown in the possible attitude to be taken by the American government in regard to copper at the beginning of the year. This is a factor that prevents active buying at the present time. Once the situation is cleared, whether at prevailing prices or an adjusted one, the way will be open for a renewal of ordinary demand, which has been materially interfered with owing to the restrictions imposed on the sale and distribution of the metal. The weaker scrap market in copper has affected the price of castings, the present quotation of 29½ cents being a drop of 1 cent per pound. The tin situation has become a little complex here over the prospect of an easier market. If reports are true, the Canadian supply on hand is more than sufficient for immediate needs, and, as a consequence, some dealers that have fairly large stocks, are a little anxious, not wishing to dispose of the metal at lower prices than what they had paid for it. The fact that the price control has been removed in England, has placed the market at the discretion of the producers, with the result that tin has dropped about $100 per ton. The export regulations, however, are still in force, and efforts are being made here by some of the metal interests to withhold the issuing of permits too freely until the situation on this side has become better adjusted. This week's quotations on tin are 2 cents lower than last week, the average price being about 83 cents per pound. The other metals are relatively quiet with the business gradually changing over from war to ordinary activities. On the whole, however, the entire situation is more or less unsettled, and will likely remain so until the turn of the year.

Little Doing in Machine Tools

Trading in machine tools has been very quiet during the past week. This has resulted from the decided action of the American government in closing up all business relative to shell production in this country. It had been thought that the initial contracts placed here would have been completed, but with the instructions to stop production by the 24th, all possibility of further activity is therefore removed. Machines that have been on order but not shipped have invariably been cancelled, particularly where these have been of a special character and adapted to shell work exclusively. Dealers are still taking on standard equipment, but general inquiry for tools is exceptionally quiet, although business is far from stagnant. Offers have been made to some plants for their equipment, but on what might be considered a scrap basis. The majority of plants are showing little anxiety regrading their equipment and are apparently in no haste to dispose of it. The supply situation is very quiet and the demand is nil for shell requirement. A much freer market is expected in regard to small tools and accessories.

Scrap Duller Than Ever

The announcement during the past week that all business in connection with American shell contracts would virtually cease before Christmas has added to the stagnant position of various lines of scrap. The present market is even more dull than that of the previous week, and dealers report nothing doing. There is now offering for sale many of the special machines that have been used for shell production, but dealers are a little reluctant in buying in this equipment. Scrap prices are all that can be obtained in event of disposal. On the other hand some manufacturers are showing no anxiety and will not talk business even from a second-hand standpoint. During the past week one local dealer purchased for scrap, the entire shell equipment of one of the smaller munitions plants here. The general quotations this week reflect the changes affecting old materials. Price changes in non-ferrous metals range from 2 to 5 cents per pound lower, and a decline of from $3 to $8 is noted on steel and iron scraps. Wrought iron car axles, listed for some time back at $40, is now quoted at $32 per ton. Boiler plates show a decline of $6 per ton, the price asked being $21 per ton. Stove plate has fallen off, the current price being $22 per ton, a decline on the week of $6 per ton. All copper scrap is down 5 cents per pound, with the market quite dull. Nearly all lines of scrap have been affected this week; changes will be noted in the selected market quotations.

POINTS IN WEEK'S MARKETING NOTES

Scrap prices quoted in this paper are merely nominal values. There are no deals going through and therefore nothing definite to judge by in the way of setting the price.

—

Nearly all the business that warehouses have been carrying in hopes of getting the steel mills to accept it is good. These orders are again being pressed on the mills for delivery.

—

A large user of steel expressed the opinion this week in writing that he preferred to buy material made in this country "even at a slightly higher price."

—

Prices of sheets are lower this week and it is intimated that shipments of boiler tubes now in transit will be put out at a reduction from present figures of five to ten per cent.

—

Munitions contracts in Canada will be out by the end of the month. Only a couple of American contracts stand much chance of surviving.

—

Pittsburgh despatches, in analyzing the present situation, are certain in their statements that there cannot be any decline to pre-war prices of steel.

—

Makers of pig iron are looking with confidence to the future. They state that there will be a greater demand for the output of the blast furnaces than there will be for steel.

—

Opinion at big American points seems to be that there will be no drastic cutting of wages. In fact the only chance for such a thing is in a swamped labor market. There is a tendency there, as here, for many foreigners to leave as soon as transportation is available, and this is counted on to take out much of the surplus labor.

PRICE ELEMENT IS NOT QUITE CERTAIN

Business Seems to Hang On That Point —Scrap Market Still Very Quiet.

TORONTO—If one were allowed to reach over and make use of a slang phrase to describe the market situation this week, it would be stated that the principal occupation seems to be the old game of "passing the buck." That is, every person admits that prices must sooner or later work to a lower level, and the whole circle of trade, from producer to consumer, seems to be engaged just now in keeping their toes well off the boards when the tumble comes.

Munitions firms are rapidly drawing their business to a close. The end of the present month will see the end of the industry in this country with the possible exception of a couple of American contracts. There also seems to be a chance that there may still be a call for fuses and adapters.

The prices that are quoted on all lines of scrap at present are simply nominal. That is, they represent the comparative values of the various lines when put up against the price for ingots. Because certain prices are quoted in another part of this paper is no guarantee that sellers can go to the yards and secure these figures for their scrap. In fact the chances are decidedly that they can not. For instance, quotations now give light copper at $20 per hundred, crucible copper at $24.50, heavy at $24.50 and copper wire at $24. This paper would change these figures if it were possible to replace them with anything that came any nearer to being the actual basis of dealing, but it is impossible to do this. Some of the dealers intimate that were copper scrap offered around 18 or 19 cents they might come into the market to buy, but at present prices they will not. The steel mills are not buying scrap either, and this tends to stop the steady flow of material through the yards. Dealers claim that mills are waiting for prices to actually some to a lower level. Many of the yards here are too well stocked with material that was taken in at fairly high prices. A dealer who has an immediate destination for material will come in the market to buy. Otherwise he will stay out, and the most of them for the present are staying out.

In Machine Tools

The sales of machine tools are not frequent at present. The situation is apparently waiting for prices to come to some sane basis. There has been a tendency in some quarters to chase up prices during the war rush. Of course, it is not going to hurt to drop this ultra-inflation, but when it comes to a point past that, there will be some difficulty. Prospective purchasers will probably be waiting for the market to return to something approaching the old-time prices of pre-war days. It is not likely that these figures will be realized, but there will be a movement in that direction and a very decided one. Machine tools right now are averaging about 75 per cent. higher than they were before the outbreak of the war. To the credit of some of the manufacturers of high grade equipment it can be said that they have not indulged in undue war profits. In other instances, though, the prices are yet too high.

There are indications of a break in the prices of some lines. It would not be safe to accept it as a sign-post of more to follow immediately, but the fact is significant and worth recording. A maker of radial drills is out with a list price of $4,700 on a machine that has been selling right along at $5,200. There has been no drop in the cost of manufacture. As a matter of fact the machines are the same as have been selling at the increased prices, and they cost the same amount of money to produce.

There is still a fair amount of business being done in the matter of supplies, and prices are not much changed.

Steel Prices Easier

It is interesting to note that nearly all the business that has been in the books of the warehouse people, is still good. There was some doubt in this regard, for in many cases it simply meant a policy of waiting until the state of the war was such that the non-essential lines could get a chance to come on the market. There has been apparently some misunderstanding that the priorities and preferences were all swept away as soon as the armistice was signed. This is apparently not correct, as the advice at the first of the week was that the export licenses were still necessary. This state of affairs will not stand very long, though, and it is only a question of days until the only open market is restored. As a matter of fact there is more old business being re-presented to the mills than new orders coming in. Firms making safes, for instance, have not been able to get into the plate market for some time, unless the orders were for a vault being put into some building that had some bearing on the war. Now, however, the prospects are that they can attend to the orders for this class of work. Makers of tanks, etc., are in much the same position. In fact some of the mills of United States that were working on war material exclusively have already intimated to their connections in this country that are "ready for commercial lines again."

A preference for Canadian material is being exhibited to a more marked degree by some of the purchasers. A warehouse sent out a list of material that was available—angles and shapes—to the trade here, and one letter from a

MONTREAL SHELL SHOPS NOT READY FOR ANY NEW LINES YET

MONTREAL, Dec. 4.—According to instructions recently issued by the Imperial Munitions Board, in compliance with a special circular from Washington, the plants here working on American shell contracts, will have until Dec. 24 to clean up on the work now in hand.

The Dominion Bridge Co. are now closing out on the final work on the old British shell contracts, and following the advice just received from Ottawa, will have about a month to continue on the U.S. orders. During the past few weeks about 1,000 men were released from the munitions end of the company's activities, and before Xmas it is anticipated that the total number affected will be about 1,600. It is more than likely that some of these will be retained in the general operations of the company, as the Dominion Bridge Co. is extensively engaged in the manufacture of marine engines and boilers, steam turbines, blowers, and other heavy mechanical devices.

At Lymburners' Plant

Lymburners Limited are just completing their American 75 mmm. shell contract, so that recent instructions affecting the general production of U.S. munitions will not be seriously felt by this company, as officials state that the entire contract will be finished in a very short time. During the past year this plant has been working exclusively on this type of shell and the average production for the past several months has been about 200,000 shells per month. About 800 men and women will be affected. Nothing definite has been decided on as to their future activities, but it is anticipated that the plant will be idle until the re-adjustment period is well advanced. Several plans have been mooted for the utilization of the plant, but no decision has been arrived at. Virtually 99 per cent. of the machine equipment adopted for shell production is of the special single purpose type adapted for shell work exclusively.

Just Getting Started

Production of the 155 mm. American shells at the plant of P. Lyall & Son will gradually taper off from now on. Forging has been stopped and the blanks now available will be machined rapidly as possible, as all operation will be discontinued before Xmas. This plant has never attained its maximum output owing to the fact that the entire enquipment had not yet been installed. No announcement has been made as to what the plant will be used for, but it is more than likely that some marine activities will be carried on owing to the fact that this firm has large shipbuilding interests now on the coast. It is possible that shipbuilding may be carried on here as the plant is idealy carried on the north shore of the St. Lawrence and adjoining the River. It is possible that some at least of the men now employed will be found employment in future activities of this firm, but temporary idleness of a great number is inevitable.

About Small Arm Contract?

In common with all other plants working on the American shells the firm of Caron Bros. will within a month discontinue the making of the 155 mm. shell upon which they have been engaged for nearly a year. A new plant had been constructed in the north end of the city and operations had almost reached the maximum. Under full operations about 1,000 men would have been employed, but this number had not been reached when the stop order had been issued. Mr. Caron stated that some complications would likely arise regarding the settlement on the part of the American Government for the work that would remain unfinished, as the work now in hand would entail considerable loss to the various manufacturers. Regarding their small arms contract for American army pistols, he stated that no advice had been received, but would not be surprised if the same ruling applied as to that for American shells.

large firm stated that they preferred to secure the material in this country, "even at a higher price."

Prices Are Dropped

Prices on sheets are put down this morning. For black No. 10, $8.50 is now quoted against $10 that has been asked for some time past. No. 28 black sheets are 25c per hundred off, selling at $8. Plates, 3-16, are marked at $8.40.

Large shipments of boiler tubes are on the way to several of the Canadian warehouses. While the lists are not handed out yet it was stated to-day that a reduction on present figures of five or ten per cent. was looked for. Dealers here can buy to much better advantage now as the makers are getting a larger supply of skelp to meet their demands. In fact several of the mills that have been out of business for the period of the war have started to roll tubes again.

The Non-Ferrous Metals.

Antimony at $16 against a previous $18 is the only drop that the local markets would admit this week. Tin is quoted locally around 85c per pound, although sales on the New York market come well under that mark.

Dealers in metals state that their trade is still quite satisfactory despite the closing down of the munitions plants. There are other lines that are in the market for material that they have not been able to secure in war days.

"We were in business before the war started, and we are in business now," was the way one of the dealers sized up the situation to-day. There is no dropping off of trade.

No doubt part of the business of the liquidation of the Imperial Munitions Board will be the disposal of some of the large properties created by it for purposes of the war. In most cases it is believed that there will be difficulty in making such arrangements, as few of the great establishments, such as that at Trenton, will be easily convertible into peace establishments, as explosive factories are never in an industrial centre, or in any centre, on account of the nature of the business.

URGES LABOR TO BE GUARDED IN ACTIONS

Tom Moore, president of the Trades and Labor Congress of Canada, has issued a letter to the trades unions, in which he announces the fact that the right-to-strike legislation of the Dominion government has been repealed, and also intimates that a representative of labor has gone to the Old Country with Premier Borden to have some part in the peace conference. Regarding the conditions in the country, under these conditions, he says:

"It is to be hoped that, with the removal of these restrictions that the unrest caused amongst the members of our affiliated organizations will subside. The best judgment and efforts of all men will be required during the future months to avoid chaos during the readjustment period of this country.

"With the cessation of war and the discontinuance of munitions manufacturing, the possibility of serious unemployment faces us. As a temporary measure, requests have been made to the Minister of Labor that all government work be placed on an eight hour day, with the forty-four hour week, and an appeal issued to other employers to do the same in order that employment can be distributed between the greatest number of workers. Other measures such as the opening up of public works and the use of day labor thereon, eliminating the contractor, and making possible the use of all grades of unemployed labor, has also been suggested to the government."

MAKERS OF PIG IRON DO NOT SEE WHERE SLUMP COMES

ALTHOUGH there has been considerable done in the way of cancellation of contracts for pig iron in the United States, there is still a very large volume of business on hand. In many cases cancellations are being refused, the idea being that it is up to the government to continue to control the situation that it brought into existence. Reports from some of the larger points in the United States give the following conditions:

Pittsburgh—The removal of all government restrictions on the shipment of iron is making it possible for the so-called less essential industries to obtain again their normal supplies of iron. A meeting of the pig iron producers of the entire country may be held soon to formulate policies for the readjustment period. Sellers of pig iron continue very optimistic as to the future and show no disposition to make price changes.

Chicago—Producers' representatives are unanimous in saying that they will accept no cancellation unless the government directs that its allocations be annulled, and to date there have been very few instances of this having been done. If allocations are cancelled it would only be fair to cancel all iron ordered for war work.

Philadelphia—Some very large tonnages are now going forward, and it appears that they have been on the books for some time, so it seems certain that there has been more 1919 buying going on in war times than was credited at the time.

Buffalo—No cancellations of any kind are reported, and one producer reports brisk inquiries for small lots, and has taken on several small orders aggregating between one and two thousand tons, foundry grades for first quarter delivery, at present prices. It is considered by many of the furnace men that the only chances for a change will be because of the coke and labor situation. With the opening of the new year it is expected that there will be plenty of business for every one.

Birmingham—Cancellations are still coming in for a considerable total. Inquiries for 1919 are still on the increase. Makers of agricultural machinery are among those who have recently placed orders. Stove works, owing to the limited supply allowed them, have a considerable amount of cast shell iron on the books that has become available, and have shown little disposition toward new buying.

St. Louis—There is no question that domestic needs are such as to keep the plants busy as they are withdrawn from government work, and there is therefore no uneasiness felt as to the continuance of activities in this district.

Cincinnati—Requests for the cancellation of foundry iron contracts with very few exceptions have been refused. Foundries in this vicinity have received a large number of hold-up orders on machine tool and other castings, and so feel justified in asking the furnaces not to crowd them with metal that cannot be used profitably. The change from war to peace work will take place without working any serious hardship.

GOVERNMENT NOT LIKELY TO ACT NOW

Will Not Take Over Any of the Property of Imperial Munitions Board

Ottawa.—Asked whether it was the intention of the Dominion government to arrange for taking over any of the property of the Imperial Munitions Board when the latter began liquidation of its business, as suggestions had been made that this should be done in connection with demobilization, Sir Thomas White, Acting Premier, said that there was no reason for doing that as none of the buildings could be regarded as suitable for the purpose.

HARD USAGE OF MUNITIONS PLANTS

Galt Manufacturer Thinks Much of the Equipment Will Have Lived Its Day

GALT, Nov. 27—Interviews with large manufacturers of munitions indicate that wherever possible an effort will be made to utilize in peace work the machinery which for some time has been producing munitions.

R. W. Roelofson, of the Roelofson Machine & Tool Co., stated that the machinery they have been using for the production of munitions will not be scrapped. Their plans are not yet fully developed, but they confidently expect to find some means of putting this machinery to good use in other lines.

A. R. Goldie, of the Goldie & McCulloch Co., stated that he did not know yet what would be done with their munition machinery, and said the question was one that was hard to decide and one on which he himself would like a little advice.

"Long runs and unskilled help have used up munition machinery more than would otherwise have been the case," said W. D. Sheldon, of Sheldons Ltd. He stated that the newer machines would be used, if possible, in other lines, but those which have been in operation for any length of time would most likely be found to have out-lived their usefulness.

CAN'T FIGURE OUT HOW THERE WILL BE A SLUMP IN WAGES

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Dec. 5.—Events as to "reconstruction" are moving rather rapidly. Reconstruction work itself is not formidable in character, for it is found to consist chiefly in ceasing to do the things that were being done as war measures, while industry is showing a strong disposition to reconstruct itself.

There is now good reason to suspect that recent talk of reconstruction was indulged in largely for its sentimental effect. For instance, at the outset it was on all hands considered imperative that the War Industries Board should continue to fix iron and steel prices, and there was much talk of the desirability of its fixing minimum prices instead of naming its prices as maximum, as formerly. The idea was that the iron and steel market was clearly booked for a great slump, and needed support for a while. The talk of fixing minimum prices was soon dropped, as it was seen clearly that nothing of the sort could possibly be done. Now there has been such further progress that it seems unlikely that the War Industries Board will set any prices at all. The present limits expire December 31, for they were as usual set to control deliveries to the end of the quarter. The board has intimated that it will fix prices only upon definite request of an industry involved, also that it will do so only in a case of emergency.

Control Relaxing

It looks now as if industry would be fairly well able to reconstruct itself, and that may be the reason why every day there is fresh news of the Government relaxing its control. It is not safe, however, to assume that it is positively settled such is the case. The relaxation of control may be due in part to the War Industries Board recognizing that the continuance of control would be difficult. Thus at the end of November the board ceased the making of allocations, announcing that thereafter the various "purchasing agencies" would make their purchases direct, the War and Navy departments, for instance, as well as the Fleet Corporation, the Railroad Administration and the purchasing commissions of the Allied Governments. Whether the initiative in this move came from the board or the buyers involved is not known. What is clear is that the authority of the board in the matter of prices is greatly reduced. Hitherto when it set maximum prices it made no particular effort to shade the prices, but placed the orders for the various requirements at the maximum limit. In future the condition would be that of the board fixing maximum limits and of the various agencies being free to seek to buy at lower prices than the limits. That they would seek to shade the limits is obvious.

Producers More Confident

Producers are showing more confidence in the price future. They do not expect the market to decline as much as they did a few weeks ago. Some blast furnace interests, though not all, venture to predict that if the pig iron market is left to itself it will advance. They claim that pig iron is stronger than steel, because in the past three years there has been more new construction of steel making capacity than of pig iron making capacity. It is true the steel works were fairly well supplied with pig iron during the war, but the foundries were not taking their usual proportion, and it would perhaps be difficult to find enough pig iron to operate all the steel works and foundries at capacity. Then it is claimed that Great Britain and France want large tonnages of pig iron, 750,000 tons being mentioned in the case of Great Britain.

The Matter of Wages

A question that has been much discussed, in connection with the future of iron and steel prices, is that of wages. It is understood that the Government does not desire to see any wage reductions and so the argument has been made that if the Government wants wage reductions to be avoided it should endeavor to sustain the market. Some criticism has been directed against the Government's policy of going slow in the matter of cancelling contracts for war steel, and what is back of the criticism is undoubtedly a desire to see conditions brought about in which wage reductions might be effected. In the last analysis, however, it is improbable that heavy wage reductions could be made. The steel mills are even now short of labor and the world's real work for the peace period has not begun. Furthermore, the iron and steel industry has in the past depended largely upon immigrant labor, and immigration has been shut off for more than four years, while prospects now are that instead of immigration there will be emigration of some of the foreign born. A great many men have signified their intention of going abroad as soon as they can secure passage. If half as many go as now think they want to go there will be a serious shortage of the class of labor upon which the coke works, blast furnace and steel mills depend. To attract American born labor in sufficient volume to make up the deficit might require further wage advances and the introduction of the eight-hour day. Steel mill labor works chiefly eight, ten and twelve hours, unskilled labor being almost entirely ten and twelve hour. Since the wage advance of last August the standard rate for common labor has been about 42 cents an hour. With the introduction October 1 of "the eight-hour basic day" the ten-hour men get paid for 11 hours and the 12-hour men are paid for 14 hours, receiving time and a half after the eight hours. At 42 cents the 14 hours is $5.88 per day, and an actual eight-hour day might be impossible at a 42-cent rate, which would make only $4.20. It must be accepted as positive, at any rate, that there is not going to be any great reduction in the wage cost of mining ore and making coke, pig iron and steel, except as some reduction occurs through men rendering better service than of late. Steel prices cannot possibly decline to the pre-war level.

The new demand for pig iron and steel is not heavy by any means. It is insistent, but is only for relatively small lots and for early deliveries. The market certainly has not struck its gait yet for there is none of the heavy buying for construction work, for "investment" purposes that is always essential to give the market full support and employ the industry at capacity. Even that part of the Government demand that is to be counted upon for the future is not much in evidence. The Railroad Administration shows no disposition to place orders for rails, cars or locomotives at this time. The Fleet Corporation has suspended some plate contracts, on the ground that the plans are being changed so that fewer small vessels and more large vessels will be built, and new specifications will be filed later against the revised program.

Predictions are of course very hazardous, but the balance of probability seems to be that something like the following will occur:

Present maximum limits for pig iron and steel products, set to cover deliveries through December 31 to continue to be observed, without the War Industries Board taking any action as to the later period; producers to endeavor to have buyers take out as much tonnage as possible of their present commitments, then to reduce prices to a level that will tempt buying as investors get ready to take hold, probably some time in the early spring, new buying being confined meanwhile to the filling of pressing requirements, against which buyers cannot afford to wait. The chief doubt is whether there will be a slump in the market, with a quick recovery, or a gradual settling to a regular trading basis on which the market will sustain itself. It goes without saying that eventually there will be heavy demand; if there is not, 90 or 95 per cent. of the trade is now laboring under a great error.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

Automotive Repair Work in the Machine Shop

Here Are a Number of Things That the Man in the Repair Shop Should Know—The Working Parts Are Very Crowded and Special Methods Are Frequently Needed to Gain the Results

By DONALD A. HAMPSON.

MACHINE shops in the repair field have naturally benfited from the widespread use of gasoline engines, particularly from the automobile. And this is not going to lessen in the future with the return to peaceful occupations and with the prospect of labor shortage for some years to come. What follows in this article applies to the automobile, but the tractor, the truck, and the stationary engine would present the same problem under like conditions—the methods applying to the one suggest other (possibly better) methods that may be used to suit particular types of construction.

Naturally most of the repair business goes to the garages. There are some garages that possess a full complement of tools and appliances, that have good machinists capable of getting the most out of such equipment, but the average garage is and should be a service station, making running repairs only. It is the writer's conviction that there should be a distinct line drawn between strictly service-and-adjustments and the work of the machinist and that this line should be maintained even in the fully equipped garage. The machinist should possess a full machine shop training, including metal working, hand and machine, blacksmithing and tool experience. The garage "machinist" does many of the things included in the above, but because he is not grounded in the theory and practice of the art of metals he cannot be expected to do or to know the how and why of all that goes to make up such a machine as the automobile—the electrical equipment, motor and carburetor adjustments, road work and repairs constituting a field that will take the most ambitious man years to master in its entirety.

It is because garage owners have not recognized the great distinction between these fields of mechanical endeavor that garages as repair shops have come into the disrepute that amounts to little else than a black eye. When machinists work specified hours, do not have to be called away for a nice fitting job to take off a tourist's muddy front wheel, and the entire force gets educated to the idea that cigarettes have no place in the day's work—then and not until then will the stigma be removed from the garage business.

Many garages do not pretend to have machine shop facilities and are the gainers by such practice; to the customer who looks askance when he learns they haven't a lathe in the garage, it is reassuring to say, "We send our machine work to Wilson & Wood's—they do the best work in town and we have special arrangements with them to get our jobs out promptly, far more so than if we had only one man around who could do such work." This arouses the customer's interest and if he does not know W. & W. he enquires and he finds they have a large shop, more machinery than a dozen "fully equipped" garages, and their men are noted for skill and honesty. A plan that has worked well for all is for a machine shop to go to a number of garages and solicit their machine work and repairs, the garages agreeing not to put in any tools and the machine shop agreeing not to give "service" or to do overhauling; when such arrangements are made and the machine shop is worthy the name, the results are mutually beneficial and the community soon places confidence in the automotive repair men.

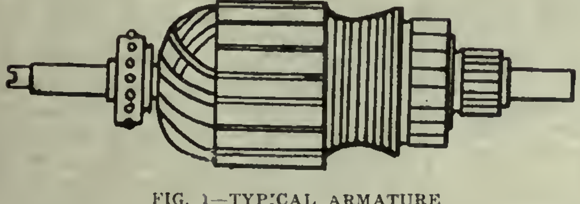

FIG. 1—TYPICAL ARMATURE

SLOTTED COMMUTATOR

SLOTTING TOOL

There is found in the modern automobile such a variety of metals in different states and the constructions are so ingenious (often so crowded), that the skill of the machinist is taxed to the limit while his interest is kept always to the point of freshness. Add to this the prodding finger of the job wanted in a hurry and you describe a field of labor to attract the most blasé. Machine shops doing repair work have a life-long experience on parts that must stand up for years and that must pass the inspection of experienced men—to them the turning out of dependable work for automobiles is but a habit extended in another direction, to which must be added the sobering thought that human life hangs on the integrity of their work.

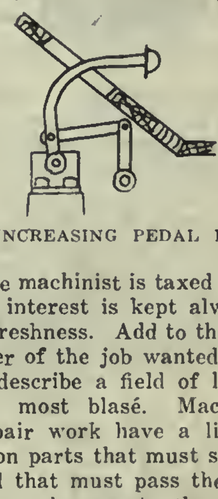

FIG. 2—INCREASING PEDAL LEVERAGE

A number of interesting repair jobs will be described and illustrated. There may be other and better ways to do each—if so, they should be brought to light for the benefit of repair men and the broadening effect of interchange of ideas—but each job has been satisfactorily done as related.

Turning Commutators

A typical armature (Delco) is shown by the drawing Fig. 1. If watched and sandpapered occasionally it will not be necessary to turn the commutators for a long time, but neglect will cause much electrical trouble and necessitate turning off a considerable amount of the copper bars. The smaller commutator gets most

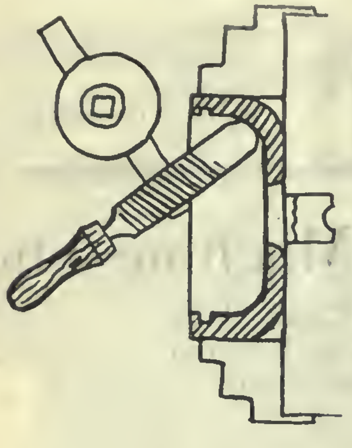

FIG. 3—HAND FINISHING BALL RACES

wear. As the brushes are not the full width of the bars, a shallow neck may be turned as shown—it makes a better looking job and assists in cleaning out the mica. Cutting the mica insulation down a thirty-second lower than the copper surface is a great help toward long life and freedom from troubles electrical.

The quickest way to remove this mica is to cut it out with a hack saw fitted

FIG. 4—BRAKE ROD REPAIR

with a handle as shown. If the mica is cut before the commutator is turned, a slip of the saw does not scratch a finished surface—if the commutator has been so slotted before, the saw merely deepens the old cut; if it has not, the best way to start the saw cuts is to notch the mica all around with a three-cornered file before slotting. The turned clearance is of great assistance in slotting. Either a blade wide enough should be used or the first cut followed by a second partial

FIG. 5 IMPROVED WAY TO INSERT COTTER

cut to cut out the full width of mica and brighten the copper sides (any mica remaining dirties the brushes). Street railway companies have special machines rigged up to slot their motor commutators.

As is well known a fine pointed tool is used for turning—and a fine feed accompanies. Sandpaper (only) is used to polish if the tool cut is not smooth enough. If a dull tool is used, nothing but a torn cut can be made—a commutator may be ruined by a tool so wide or so dull that it gouges the bars. With the right kind of a tool, a smooth cut is obtained on the narrowest of bars and with the mica backing already removed. The large commutator seldom needs more than a light sandpapering; its bars are wide—19 against 38 in the small commutator on this Delco—and the brushes less wearing. The machinist of experience sees to it that the centers are true before he turns and that there are no imbedded copper chips after he is through to cause a short circuit.

Making an Easier Working Clutch

The sale of a car hinged upon the question of whether the clutch could be made easier working or not. The customer was a man of importance in the community, also he had a "bum knee." After the garage people had freed up the adjustment to the slip point and had removed joint friction all without helping the trouble, the machine shop was consulted. Viewed from their angle it was found that of the five inches pedal movement but one and one-half inches were actually needed to release the clutch. Then the draftsman took some measurements and roughly laid out the change of Fig. 2.

The old pedal was cut off so as to be entirely under the floor board. A new pedal took its place as the foot "connection" and though it traveled through a different arc, it mattered not to the customer because he wasn't familiar with the original one. A stud set in a piece of steel angle supplied the pivot for the new pedal, the angle fastened by using longer bolts through the sub-frame. With this arrangement nearly all of the five inches movement was utilized in releasing the clutch. Taking advantage of the fact that most drivers shove the pedal clear to the floor, this increased leverage made the clutch so easy as to be perfectly acceptable.

Finishing Ball Races

Once in a while circumstances force the making of a ball cup or cone in the machine shop. Because of the uncertainty in hardening and the meagre grinding facilities, such work is avoided when possible. Usually the concave surfaces have to be left as turned—therefore they should be very smooth and nicely rounded. After turning with a tool, a hand tool is excellent to finish the contour more perfectly and to smooth down. If coated with blue and a ball held against the revolving piece, the high spots are located — then the hand tool resting on a piece in the tool post is used to scrape the surface down for another trial. This method gives better results than any other possible with ordinary equipment. The hand tool may be made from an old file which before rehardening is shaped relatively close to the curve of the ball.

Brake Rod Repairs

Brake rods frequently snap in two, the break occurring about in the middle of their length where the "slap" is greatest and being very nearly square across. The usual repair is by a weld. Some people are opposed to a weld in so vital a part; also at times there is no one at hand who can make a good weld—a weldless repair is made as follows:

Cut a thread on each of the broken ends. Usually this will be 5/1" or ⅜ x 24. Get a piece of steel ½" or larger, drill and tap clear through with the corresponding tap. This piece should be not less than 1" long and may be hexagon or round. Screw both ends of the rod into the nut until they butt and the rod is the same length as in the original and all ready for service. Such a repair is quickly made—it necessitates no re-adjusting of the brakes. As the length of such rods is several feet they get much

FIG. 6
WHERE TO CUT OUT. IN POSITION.

vibration, a cause that may be remedied by fastening a light coil spring between the floor boards and the middle of the rod with the result that the rod is constantly snubbed, but its normal function is not interfered with in the least.

Needle Valve Work

Carburetor needle valves need occasional attention. If grinding is necessary, pumice stone should be used in powder form. Ford owners who have tried it report greatly decreased gasoline consumption from a change in shape of the pointed valve end. If the point is filed to give a lesser included angle, this economy is noted. A precision lathe or a small lathe and chuck in first class condition are necessary for needle valve work.

A Kink for Castellated Nuts

A castellated nut seldom lines up with the pin hole when the nut is tightened "just right." Common practice is to set up a little tighter, making the bearing too snug and perhaps straining the bolt or else to slack back to the next hole, when the bearing is too loose. On the best work the nut is taken off and the face carefully filed an amount (determined by trial) that will let it turn up about another twelfth of a revolution, which will bring slots in line with pin hole when the bearing fits as it should be.

Inserting Cotters in Unseen Holes

We have cotter pin extractors and a few inserters on the market, but the latter are not of assistance in crowded quarters and for unseen holes. For general work and particularly for these holes that must be felt and not seen, the kink shown by Fig. 5 is invaluable. Instead of inserting the cotter flat against the shoulder, it should be turned at right angles. This brings one leg against the work and the other springing outward where it is convenient to the finger for closing. A maximum of finger room is thus afforded, a sharp contrast to the conventional method where fingers should possess tweezer properties in addition to the sense of touch.

Quick Way of Making Thrust Washers

Special washers, or collars, are often wanted to back up gears after adjustments. Some shops make them from a round piece of steel, chucking the piece, drilling, and cutting off to the required thickness. A simpler way is to make up the space with one or more washers of standard thickness cut from flat cold drawn steel. Thus if a space of 7/32" was to be filled, it would be done by one washer each of ⅛", 1/16" and 1/32" thickness or other combination according to the steel at hand. A dollar's worth of steel of thicknesses under an eighth would make dozens of washers for rear end work—an unskilled man can make good washers that way as well as an experienced lathe hand can make the single piece kind.

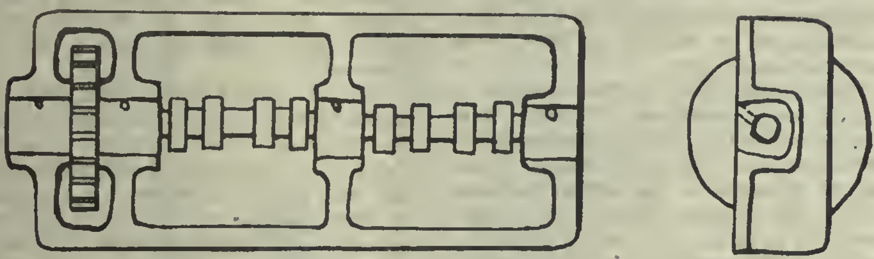

FIG. 6—BABBITTING BLIND BEARINGS

New Rings for Worn Cylinders

The writer prefers the straight lapped rings for worn cylinders instead of those diagonally cut. With the latter there is of necessity a leaking space provided if the rings are not fitted tight together at the ends, and if this is done there is danger of rings being so tight as to score. With the straight lap, the rings could take up a sixteenth of an inch difference in circumference (if it were there) at different parts of the bore and still there would be no crack exposed for compression to leak past. And it is as easy to cut the rings that way as on the angle as shown by Fig. 6.

A Blind Construction and its Repair

A certain well known make of popular priced cars has a removable side plate for the cran case and this "plate" carries the cam shaft in four babbitt bearings, the two at the front end enclosing the timing gear as shown in Fig. 7. There is no means whatever for taking up wear in the bearings, though that may not be necessary in the normal life of the car and need not be considered. But when the timing gear needs to be replaced "you are hurt," in shop vernacular, for the babbitt bearings are not renewable linings but are cast in the side plate which is provided with liberal anchors to keep the babbitt in place. Broken and worn gears do have to be replaced. What to do to avoid re-aligning and pouring after the entire shaft and bearings have been removed has puzzled many a workman.

Instead of taking out all the babbitt at each bearing, it can be carefully chipped and sawed down to the center line of the shaft, when the latter may be lifted out. The gear is then changed and ready to go back. If the pockets for babbitt are carefully cleaned and the anchor holes drilled out and the "parting line" filed down smooth with all swells and burrs taken off the bearing surface, the shaft may be laid back in its original position. Then the pockets are blocked up in the usual way and the upper half of the bearings poured. The anchor holes effectually keep the new metal in place.

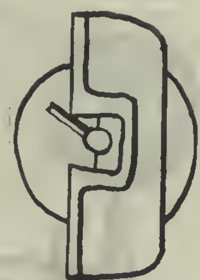

FIG. 7 WORK ON A BLIND BABBITTED CONSTRUCTION.

It is possible to make a first class job in this way, a running fit in spite of the fact that the shaft cannot be taken out for reaming or scraping of the bearings. A coating of red lead or of graphite mixed with oil will leave the babbitt running fit but not too loose. For the oil holes in each bearing, pieces of wood or of 3/16" rod are put in the mould before pouring and supported at the right angle by putty; these are withdrawn after the babbitt solidifies, leaving a clean hole right up to the shaft. Such a process makes a short job of what appears to be hopeless case in the beginning.

Increasing the Size of Cast Iron Parts

If cast iron is heated to a red and kept at that temperature for some time its size is permanently increased. The increase is only a matter of a fraction of an inch—usually but a few thousandths—but this is often enough to permit a light cut over a part and still leave it larger than it was originally, thus saving a worn part like a piston and getting that much more wear from it. An hour's heating will produce a measurable increase in the size of a worn piston casting.

Reaming Undersize in Cast Iron

There are several well known methods for making a reamer cut larger than itself—but rarely do we hear of any way to make it cut smaller, except the one to wait until the reamer wears. But when a hole is wanted one or two thousandths small and the material to be cut is cast iron, this can be done by the use of oil during the operation. Cast iron is always reamed dry, but this trick will make even a sharp new reamer cut a shade small and with a reamer slightly dull, the oil will produce a hole noticeably smaller. In fitting wrist pins, this is a time and labor saver.

A Tool for Enlarging Holes

The need for some sort of a tool other than a file for enlarging holes is feln almost daily in the repair shop. Sometimes it is a job in the vise, sometimes it is a job on a car on the floor—usually the work is not particular, often it is desired to enlarge an eighth of an inch or thereabouts. If there is a railroad shop in the vicinity get the boilermaker to save an old boiler reamer for you. These are long taper reamers, a typical size being about ¾" and 1¼" at the ends and 15" long. They are sharpened until the flutes are nearly gone and in the course of use may acquire some broken teeth, but they are tough and very useful when a hole needs to be enlarged, as, for instance, a hole in the side frame of an automobile. Enlarging such a hole with any sort of a breast drill is mean, catchy work, but the taper reamer will do it quickly and easily. And the taper is so slight as to be negligible

Before Buying a Gas Saver

Machinists on automobile work are frequently asked their opinion of the saving effects of one of the gas mixers advertised to break up the mixture of air and gas before it gets to the cylinder. For less than a dollar one may try this out before buying.

If a ¼" pipe tap is put in the "Y" of the intake and a pet cock inserted, the effect of more air can be noted—and this comes pretty near to giving the result obtained by the patented articles though it is not automatic or convenient to regulate when driving. However, if it does no good the cock may be left closed and everything is as before—if it does show a betterment, the hole is all ready for the mixer which usually attaches at that place.

Saving Time With New Ring Gears

Before riveting on a new master gear to the spider, it is a good plan to put the latter in the lathe and check the seat where the ring goes. Often an unsuspected high or low spot or a bend will show up which if unnoticed would cause the gear to run out and be the real source of much trouble and noise, hunted for in vain.

Two Items of Equipment

The shop that has city gas service cannot afford to get along without a bunsen burner fitted to at least one jet. These burners produce a hot blue flame that does not leave any soot; they can be bought of the gas company, who will make any change required to give the right kind of a flame for particular conditions. The gas flame makes the finest kind of a medium for drawing the temper on hardened parts, for tempering small tools, for annealing wire, bending springs, and a hundred other jobs requiring a clean, hot flame instantly available.

City gas is useful in another way. We are told that gasoline conservation demands other methods of cleaning automobile parts than washing in gasoline and that soda is the right thing to use. But soda requires heat and a convenient, clean heat supply is not always at hand. It will pay to rig up a soda cleaning outfit—the cost is really very slight. An ordinary gas stove burner is inexpensive and so is a good sized iron kettle for the soda and the work. For safety and neatness these should be surrounded by a metal cylinder which may be a section of an old hot water tank—with it, a couple of cross pieces can be put in which will take the weight off the burner. With this self-contained outfit, all the grease may be boiled off small parts and gears at little expense and the fire can be started any time with no trouble.

SHAFTING QUICK TO CATCH CLOTHING

Great Care is Always Necessary to Guard Against Any Accidents.

By J. H. R.

The statement that an oiler employed at the Hochelaga power plant of Montreal Tramways Co. was recently killed by being swung around a driving shaft and dashed to the concrete floor, only emphasizes the fact that the greatest precaution must be continually exercised when men working in close proximity to rapidly moving shafts or machinery. The presence of oil on a revolving shaft is always an attractive force for loose parts of clothing, and little warning can be given when a shaft takes hold of some portion of the wearing apparel.

We would recall a instance where the driving shaft of a geared draw press was located at the rear of the machine, at a height of about five feet from the floor. When setting or repairing draw dies it was frequently necessary to stoop beneath this shaft to reach the work, and the writer himself has had cause to remember this shaft, as it has been the means of pulling a few odd hairs out of a well cropped head. Chances should never be taken where risk is imminent. Play safe.

METAL HARDNESS TESTERS

By F. C. P.

THE accompanying illustration, Fig. 1, shows a metal hardness testing machine of the hydraulic type, developed at Pittsburgh, Pa., while Fig. 2 shows another type of hardness tester of Waldo type using plummet weighing one pound and falling one foot to the surface of the material whose hardness is to be measured.

In the drawing Fig. 3 may be noted the details of construction of a microscope designed to read Ball Test Impressions, as utilized in connection with the hydraulic testinb machine on the Brinell principles for determining hardness of metal, as developed by Eimer & Amend.

It may be of interest to consider the construction and operation of these hardness testers, as utilized in various industrial laboratories.

For the inspection of the hardness of metals under conditions of service, various instruments have been proposed by physicists and engineers, whose fundamental principle is the actual deformation of the material tested, by a uniform blow. It is claimed by some that instruments which measure the skin elasticity of materials rather than an absolute deformation of their surfaces, have found less favor with engineers and are usually limited to inspection of material of identical chemical constitution and uniform working. Instruments which actually deform the surface are usually limited to laboratory installations and are heavy though leaving little to be desired on account of their accuracy, certainty of duplicating results and facility of use.

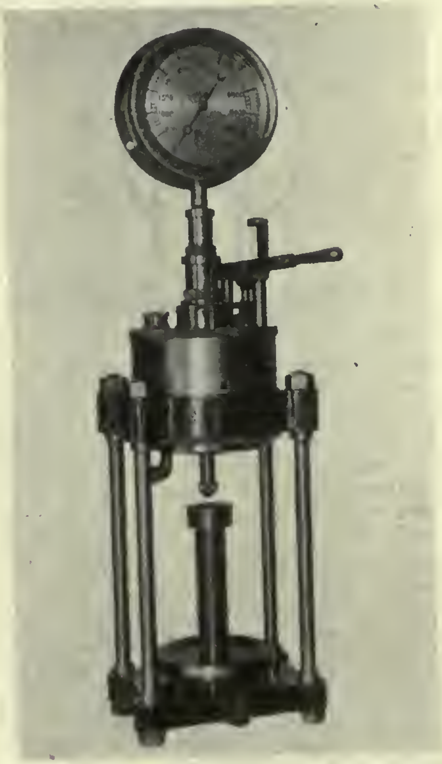

FIG. 1—HYDRAULIC HARDNESS TESTER

The instrument the writer describes, noted in Fig. 2, consists essentially of a plummet weighing one-tenth of one pound avd., and falling one foot to the surface of the material whose hardness is to be measured. This plummet has a conical, replaceable, chill-tempered, 60 degree, steel point.

It will be seen that this plummet has tied to its upper extremity a very thin silk thread which bends over a funnel-shaped end piece, into which slotted holes are cut with burnished edges so that the silk thread passes through them with practically no friction loss. The funnel turns with a slight friction in the end of the jointed supporting brass tube. The silk thread is attached to a small burnished ring at its lower end, which ring in turn is caught in a little trigger, which can be released by a thumb screw without jarring the instrument.

The silk thread then passes from the release catch through the holes so that the plummet point is exactly over the aperture in the base of the instrument. The base of the instrument is supported on three points, two of which are controlled by a levelling screw and small cross levels indicate the verticality of the supporting rod.

When in use, the instrument is set on the surface of the material whose hardness is to be tested, so that the aperture in its base is concentric with the exact spot to be tested. The plummet is then hung as shown, and lowered by holding the silk thread by its ring between the fingers so that the exact position of the clamp may be found for insuring the vertical fall of the plummet. This being determined, with the instrument levelled. the thread ring is placed in its releasing trigger and with the plummet in position the funnel support is gently turned until the distance from the conical point to the surface of the material to be tested is exactly one foot. The instrument is now ready for use.

A convenient way of stopping any slight swinging motion of the conical point is to touch it gently with a small camel's hair brush or a piece of cotton wool. The instant the plummet is still the trigger is released by the thumbscrew, and the plummet falls, making a uniform circular indentation in the material tested. The object in releasing the plummet from the bottom of the apparatus, is to avoid any disturbance in its upper support. The entire operation consumes but a few seconds after a slight experience with the instrument.

The small portable microscope noted in Fig. 2 then replaces the plummet apparatus. This microscope is designed so that it has sufficient illumination and magnifying power to measure easily with an eye-piece micrometer the diameter of the impression made by the falling plum met point. The average diameter of the circular depression is then measured Scale for measuring indentations is embodied in the microscope.

Many consider the Brinell method of testing the hardness of metals as the best method. A hardened steel ball is pressed into the smooth surface of the metal so as to make an indentation which is then measured with the aid of a microscope. The Brinell Ball Test may be applied to unfinished material as well as to manufactured goods, such as rails, armor plates, guns, projectiles, automo-

FIG. 2—PLUMMET HARDNESS TESTER

bile springs and structural materials.

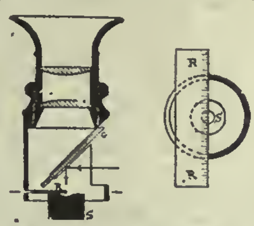
It will ascertain the effects of annealing and hardening of steel and serves as a basis for calculating the tensile strength directly from the results of the hardness test. Another factor in the Brinell method is the ability to measure the power of resistance of various metals to continuous pressure. For practical purposes the tensile strength can be assumed to be one-third of the hardness number in metric units; or the hardness numerals can be multiplied by the coefficient of 0.346 as a uniform constant and the result obtained will be the ultimate tensile strength of the material in kilograms per square millimeter. To convert kgms. per sq. mm. to pounds per square inch, multiply by the factor 1422.3.

The hardness tester shown in Fig. 1 has four supporting columns, but the Eimer & Amend machine is of the heavy goose-neck style. By the use of the controlling weights wrong readings are entirely excluded. If the manometer should get out of order this device will show the error. The main parts of the testing machine are: The Hydraulic Press, the Hand Pump and the Pressure Gauge with the attachment for the controlling weights.

In order to fill the machine with oil, care is taken to remove all air. To do this the gauge is left off and the pump used till the clear liquid shows where the gauge is to be screwed on. The latter s filled with oil before shipment is made. If the pump, piping, press or gauge contain air, the gauge hand will travel up and down, and the pump lever has a tendency to rise. The gauge hand will remain in any position if the machine is free of air. The machine utilizes 10 mm. steel balls and a microscope, and hardness number schedule.

As noted in drawing Fig. 3, the microscope used is especially constructed to real Ball Test Impressions. The reflector G furnishes a strong illumination for the test pieces, and with the aid of the small steel rule R fitted in the bottom of the cylinder the exact diameter can be very easily read to 1-10 of a millimeter. The instrument can also be used where accurate measurement of small distances is required, and by removing the glass reflector and steel scale the magnifier may be used as an ordinary focusing glass.

The test piece must be perfectly plane and even on the spot where the impression is to be made. It is then placed on the press table and brought in contact with the ball. Then it is only necessary to close the valve and with about ten strokes of the hand pump a pressure of 3,000 kilograms (6,614 pds.) is produced. Iron and steel are subjected to this pressure for ¼ minute, softer material for about ½ minute. After this time the valve is opened, the oil re-enters the reservoir and releases the test piece. The diameter of the impression is then measured with the aid of a microscope by which an accuracy of 1-10 mm. can be obtained, and now the corresponding



MICROSCOPE FOR READING INDENTATION IN DETERMINING HARDNESS

table furnished. The small quantity of hardness number is looked for in the oil which may leak through the press cylinder collects in a cup and is periodically returned to the cylinder.

SHIPPING DEVELOPMENTS AT BELFAST

Definite and most interesting information as to the shipbuilding developments, now under way at Belfast, was communicated by the chairman of the Belfast Harbor Board at one of its recent meetings. During the past year about 150 acres of the harbor estate on both sides of the river Lagan have been let to the local shipbuilding firms, representing almost a doubling of the area presently devoted to shipbuilding and marine engineering. About 124 acres have been let to Messrs. Harland and Wolff, Ltd., and 24 acres to Messrs. Workman. Clark & Co., Ltd. On an area of 85 acres of recently reclaimed land on the east side of the Musgrave Channel, Messrs. Harland and Wolff's contractors are now laying out a new shipyard, erecting workshops, and the necessary overhead equipment. The water frontage is over 900 ft., and there is accommodation for six building berths on which it will be possible to construct vessels up to and over 1,000 ft. On another area of 40 acres, situate between Musgrave Channel and Queen's Road, the same firm intend laying down premises for engineering purposes. Messrs. Workman, Clark & Co., have acquired 24 acres for extensions to their North Shipbuilding Yard supplementary to their extension carried out about five years ago, in which the firm then laid down two building berths, and to utilize the rear portion of the new ground in various ways necessary to the carrying on of a shipbuilding business. The firm has a present twelve building berths, five of which are in the south yard on the Co. Down side, which is undergoing reorganization. Side by side with this private enterprise, the Harbor Commissioners are embarking on a most extensive scheme of harbor works, including wharves and jetty quays, deepening of channels, etc., the carrying out of which will be spread over a considerable number of years. Parliamentary powers, involving an expenditure of 2½ million pounds on these works, which also include the construction of a new graving dock, 975 ft. long, and an entrance width of 111 ft., have been obtained during the present session.

THE LARGEST MOTOR BOAT

The largest and most powerful motor ship yet produced anywhere was, in September, put through her speed trials on the Clyde. This is the twin-screw Deisel-engined "Glenapp," of 10,000 tons deadweight carrying capacity, and 6,600 total engine power, developed in two sets of eight-cylinder, four-cycle Burmeister and Wain (Diesel) Oil Engine Co., Glasgow. The vessel herself was built by Messrs. Barclay, Curle and Co., Whiteinch, who previously were associated with the Burmeister and Wain works, and were pioneers in Great Britain in the matter of motor ships. All the engine room auxiliaries of the Glenapp, also all deck machinery. including the steering gear, are electrically driven. the power being generated by two auxiliary Diesel sets in the engine room. A small oil-fuel boiler supplies steam for heating and cooking systems, and for fire-extinguishing purposes. The oil-fuel is carried in the vessel's double bottom, the space generally occupied by side and cross coal bunkers being thus available for cargo. It may be added that Messrs. Barclay, Curle & Co., Ltd., during September, and within a period of ten days, delivered to their owners two merchant steamers of a total deadweight carrying capacity of 20,000 tons.

Halifax.—A contract has been given the Halifax Shipyards, Ltd.. for the building of two 10,500 tons d.w. steel steamers. The price paid is $197.50 per long ton d.w. The vessels are to be built to British B.O.T. Canadian Steamship Inspection, and Lloyd's requirements.

Notes on the Computing of Gauge Tolerances

This Article is Based on Practical Accomplishments and is Applicable to Every-Day Practice—Rules Are Given For the Computing of Allowable Tolerance For Various Gauges

By M. H. POTTER

IN considering the design of gauges it must be borne in mind that they are the direct opposite of the cutting tool. The tool removes stock and leaves a surface. The gauges perform no work themselves but check work already done.

The tool does only one thing; the gauges must oversee everything and overlook nothing.

As one weak link may break a long chain, so in manufacturing a complicated, interchangeable part, any operation not completely controlled by its gauges may utetrly disrupt production or cause interminable delay in getting started.

The following are some of the more frequent troubles experienced with gauges:

1. Each individual gauge must tell a true story. If it is to be used by inexperienced girl inspectors it must also be as near foolproof as possible. Many gauges give a false reading by attempting to cover too many points, particularly on the "no go" end.

hole within these limits will accept the "go" and refuse the "no go" end, and so also may an oblong hole, a diamond-shaped, or even, in an extreme case, a round hole, which is absurd.

Much better gauges for this purpose are a double-ended width gauge and a single-ended square plug, such as gauges width gauge has on one end the maximum size, and, if it enters, the hole is then at least large enough. The thin width gauge has one one end the maximum distance between opposite sides of the square. If this will not enter, then the hole is not too large in any one dimension, and consequently is acceptable. The "go" end of the width gauge is used when the square plug will not enter, and indicates which dimensions are below size, or whether the plug is hanging up on corners, etc.

The "no go" part of a gauge should check only one dimension. When it attempts to check more than one it is evident that should any one of the several dimensions be correct, the part would

assigned and yet be troublesome at a later point when assembling. If each gauge tells a true story and the tolerances are properly computed, then a careful investigation will usually show that at least one operation is not completely controlled by its gauges.

A case of this kind is a part similar to Fig. 2, having several dimensions, each of which is given definite limits. When these dimensions are gauged separately it is possible for every one of them to be within the prescribed limits, and yet for the part to give trouble at assembling. In this particular case a combination gauge similar to the part with which this must assemble will assure that a part meet this combination gauge and having each of its dimensions within the given tolerances will be satisfactory.

Examples of incomplete gauging are innumerable. Bar stock cut to proper length for machining will not clean up unless the ends are square, yet how much labor and material has been lost because

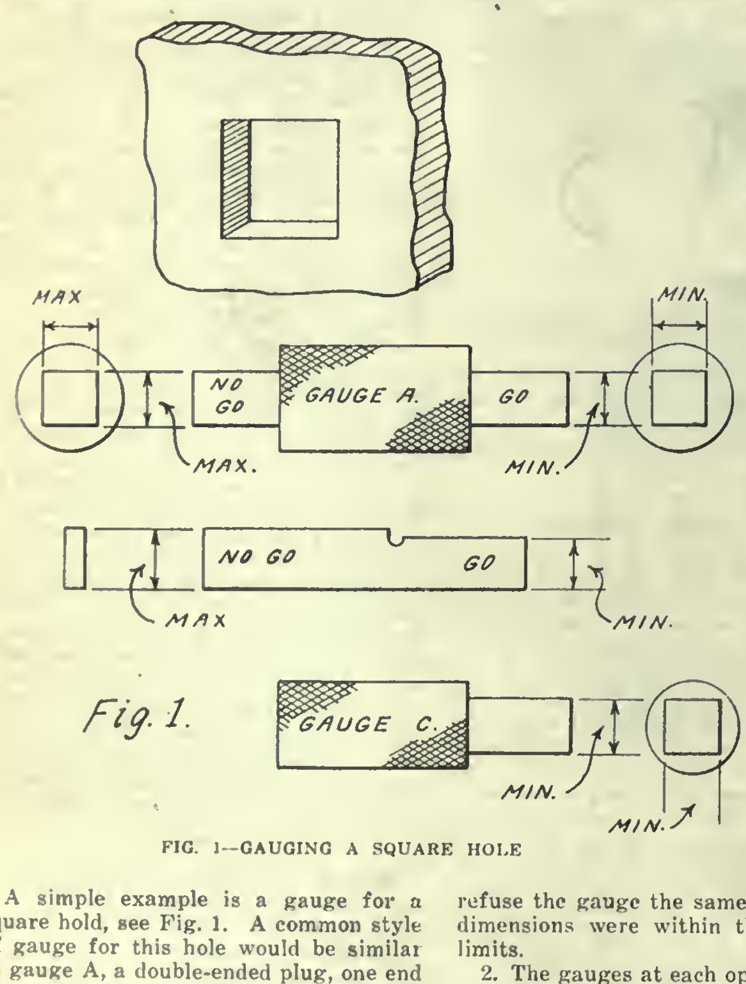


FIG. 1—GAUGING A SQUARE HOLE

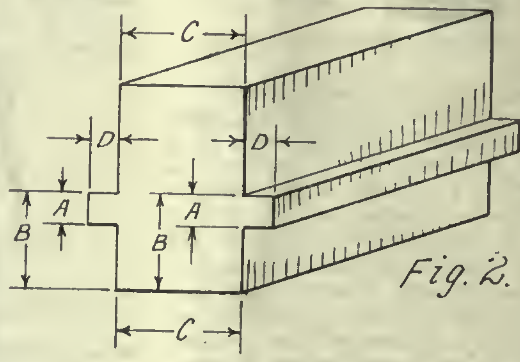

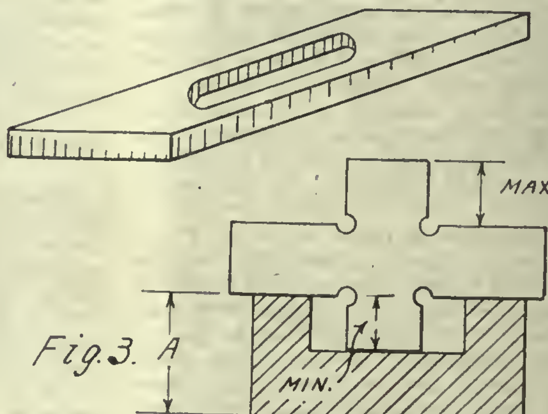

FIG. 3—DEPTH GAUGE

A simple example is a gauge for a square hold, see Fig. 1. A common style of gauge for this hole would be similar to gauge A, a double-ended plug, one end having the minimum and the other the maximum size of the hole. A square

refuse the gauge the same as though all dimensions were within the established limits.

2. The gauges at each operation should tell the whole story. Under certain conditions parts may meet all the gauges

the cutting off was done to a length gauge and not to a square gauge.

In drilling holes throug material of any considerable thickness, both ends of the holes must be checked, for though the holes may start properly they are liable to be out of location when they get through to the other side. If both ends are gauged the operator will learn to control the cut or get another job.

Errors of this nature are perhaps the most persistent and vexatious experienced in manufacturing interchangeable parts. They are errors of omission rather than of commission, and therefore extremely difficult to locate and overcome.

3. All of the points gauged at any one operation must be within the control of that operation. Can you imagine anything more discouraging to a workman than to adjust his machine painstakingly, complete a tray of work, and then find that a large percentage of the pieces must be scrapped? To have one piece perfect and the next way beyond the gauge limits, both off the same machine and at the same cutting?

In Fig. 3 is shown an example of this error. Here is a flat piece with a recess cut into the top. In making this cut the part would usually rest on its bottom surface yet the simplest and perhaps the most likely gauge would measure from the top surface. Any variation in the thickness of the piece would endanger its meeting this depth gauge, although the thickness is entirely beyond the control of the last operator. If the machine is adjusted to cut properly on a part that is near the minimum thickness and the next part is up to the maximum, the cut will be much deeper and possibly beyond the limit of the gauge.

One peculiar danger in this condition lies in the fact that with great care a moderate production may be maintained without serious loss. In the example shown in Fig. 3 the workman who establishes the thickness and the one who makes the recess cut may, by close cooperation, arrange their work so that the result will come within the limits of the gauge. When, however, production increases, and especially when a night shift is started, this close co-operation is lost. The width now varies the full limit of the gauge, and the operators cutting the recess begin to lose time and patience, while production becomes seriously impaired.

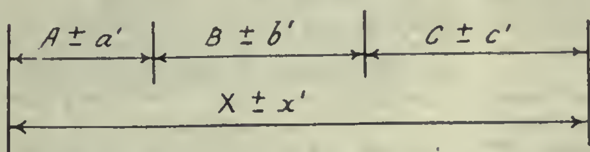
The worker is unjustly penalized and production is on an uncertain footing when one operation is dependent for its success on the accuracy of another operation not performed at the same time or under the same control.

4. The operator should be allowed the full limits of his gauges. In munitions work the limits on the finished parts are specified and are not within the control of the manufacturer. The operations and equipment must be laid out to meet these established conditions. Unless the manufacturer appreciates that every cut will vary independently of every other cut, and allows for this variation, he may be compelled to resort to the subterfuge of preferred tolerances. In other words, give an operator a gauge with .005 inch tolerance and tell him to work to the high side. This is an absurdity, nullifying at once the object and purpose of limit gauges. Provided the limits set by the Government are within reason, it is nearly always possible through careful study to give every operation definite workable tolerances.

In a way the computing of tolerances is a special branch of munitions, which, for a lack of a better name, might be termed "the study of variables within limits." It is controlled by a few simple rules that are almost self-evident, though apparently often disregarded. Some of these rules may be given as follows:

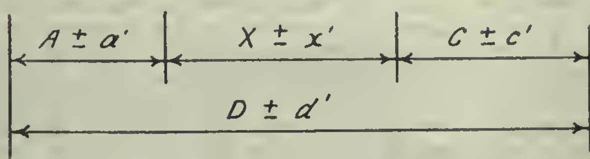
Rules for Tolerances

Rule 1. Any dimension comprising two or more dimensions, each of which may vary within certain definite limits, will be subject to a possible variation equal to the sum of the variations of all the component dimensions.



Maximum overall length =
$X + x' = A + a' + B + b' + C + c'$
Minimum overall length =
$X - x' = A - a' + B - b' + C - c'$
Possible variation or tolerance =
$2x' = 2a' + 2b' + 2c'$
Mean overall length $= X = A + B + C$
½ maximum + mimimum

Rule 2. When an overall dimension and all but one of the component dimensions are assigned definite limits, the possible variation of the remaining component is equal to the sum of the tolerances of the other components plus the tolerance of the overall dimension.

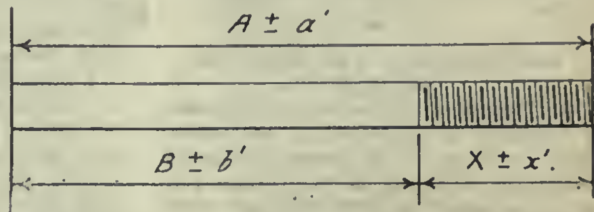


Maximum length of remaining component
$= X + x' = (D + d') - (A - a') - (C - c')$
Minimum length of remaining component
$= X - x' = (D - d') - (A + a') - (C + c')$
Removing parenthesis, first =
$X + x' = D + d' - A + a' - C - c'$
Removing parenthesis, second =
$X - x' = D - d' - A - a' - C - c'$
Possible variation or tolerance
$= 2x' = 2d' + 2a' + 2c'$
Mean length = ½ (maximum + minimum)
$= X = D - A - C$

A practical application of these two rules is that tolerances should never be given to all the dimensions forming a closed circle unless the tolerance on some one dimension is equal to the sum of the tolerances on all the other dimensions.

Another application is that when a dimension is obtained by several independent cuts, the limits given to these cuts must be such that the sum of their tolerances is equal to or less than the allowable tolerance on the resultant dimension.

Rule 3. The amount of stock left by a roughing cut for removal by a finishing cut is never a definite amount, but is variable with a possible range equal to the sum of the tolerance of the rough and the finish cuts.



Maximum amount left for finish cut
$= X + x' = (A + a') - (B - b')$
Minimum amount left for finish cut
$= X - x' = (A - a') - (B + b')$
Removing parenthesis, first
$= X + x' = A + a' - B + b'$
Removing parenthesis, second
$= X - x' = A - a' - B - b'$
Difference between maximum and minimum $= 2x' = 2a' + 2b'$
Mean depth of finish cut, ½ (maximum + minimum) $= X = A - B$

It is so usual to say, leave on .015 inch for a finish cut, that many engineers overlook the fact that the amount removed by this finish cut will more likely vary from .005 to .025 inch. This is an especially serious error when some other point is related to the rough surface, and then, when the finish cut is made, is assumed to bear the same relation to the finished surface.

Possible modifications of these rules are legion, yet practically all gauging problems can be solved by the application of these three. These in turn are all based on one great principle, namely, "Whenever a dimension is determined by two or more elements it is subject to a variation equal to the sum of the variations of all the elements concerned."

The importance of gauging has long been recognized in this country. With the war has come the need of not only making duplicate parts, but of making them in accordance with prescribed limits and specifications. The experiences of the last few years have brought home to most manufacturers of machine shop products a realization of the difficulties attendant upon analyzing these requirements; establishing the locating points and sequence of operations, and designing gauges to control in the actual work, the methods determined in the drafting and engineering departments.

Only by completely controlling each operation through the correct use of proper gauges can manufacturing difficulties be localized and the full talent of the organization employed to overcome them and facilitate production to the fullest extent.

KNOCKING IN GAS ENGINES

By M. M.

A knock in a gas engine is frequently a warning of approaching breakdown. For this reason, it is generally inadvisable to allow an engine to continue running a moment longer than it absolutely necessary when a knock is heard. It would be interesting to know how many disastrous breakdowns, entailing personal injuries and stoppages of work, might have been prevented, had the engineer-in-charge not failed to heed the warning given by a knock in some part of the engine.

In probably the majority of cases, knocking is the result of lost motion in some part or other of the engine. For instance, the connecting rod brasses may have become worn, or the fly-wheel keys may have worked loose, and so on As a general rule, the first thing the average engineer does when he discovers any knocking, is to close up the big or the small ends of the connecting rods, or both ends if necessary, and in many cases this will cure the trouble.

It will occasionally happen with large engines, however, that, after fitting new connecting-rod brasses, a new and heavy knock will develop in the engine cylinder. This may usually be accounted for in the following way: The continual motion of the piston to and fro in the cylinder has worn away some of the metal of the liner, leaving a ridge at the part where the first piston ring moves up to each stroke. Since the new brasses are thicker than the old ones, the effect is to cause the piston to move a little further up into the cylinder each stroke, with the result that the first ring strikes against the ridge each stroke, causing a heavy knock. Of course, if the engineer in charge has taken the precaution to fit liners behind the brasses, as wear has taken place, so as to maintain the correct centres, the trouble in question is not liable to arise.

To prevent this new knock, it will be necessary to remove the ridge referred to by chipping and filing. If it be impracticable to do this early, the first ring may be removed from the piston until such time as the true remedy can be applied.

Sometimes the piston rings themselves will cause knocking or rattling through their being loose, and it is not always an easy matter to trace the knocking caused in this way. When, therefore, a knock cannot be at once located, it is advisable to test if the piston rings are a good fit in their grooves.

Looseness of the fly-wheel keys is a somewhat common cause of knocking in gas engines. The conditions of working in a gas engine are of course severe, much more so than is the case with a steam engine, and with the increased pressures and speeds now in vogue, it is no easy matter to get the keys to remain tight for long periods of running. The slightest amount of slackness is obviously serious, as in addition to giving rise to more or less severe knocking, it involves risk of damage to the keys, and fracture of the wheel boss, and possibly the crank shaft. Loose keys are always liable to be met with if the wheel boss has been bored slightly too large or at all out of true.

It is not sufficient that the fly-wheel keys be quite tight, but they must be a perfect fit. In numerous instances, the keys have been found as tight as possible, but the fly-wheel was, nevertheless, slightly loose, and a heavy knock occurred in consequence. An interesting example presented itself, when a large gas engine was reported to be knocking, and the owners, who were unable to locate the knock, arranged for a firm specializing in engineering repairs, to look into the matter. The firm's men commenced their investigations by first removing the connecting-rod and piston, with the object of closing the brasses, but this was found to have been done already by the owners. The piston-rings were next examined for slackness or breakage, but these were found to be in good condition and to fit perfectly. The fly-wheel key was then examined, but proved to be quite tight. As the cause of the knock could not be located, those concerned decided to give the engine a thorough overhaul, yet after the work of overhauling had been completed, the engine, on being started up again, knocked as badly as ever. The cause of the trouble was, however, discovered shortly afterwards by chance. The engine had been stopped again, and the man in charge of the job happened to place his foot on one of the arms of the fly-wheel by way of a rest, and in order to think the matter over. Whilst in this attitude the man felt a distinct knock on the sole of his boot. This gave the clue to the solution of the trouble; obviously there must be some slackness or lost motion in the fly-wheel. Although the key had previously been found quite tight, a close examination of the key and its keyway were now made, and the examination served to show, not only was the key badly proportioned and badly shaped, but the keyway had been badly cut, being narrower in the middle than at the ends. In short, only a short length of the key was really effective in securing the wheel to the shaft, and this was the cause of the whole trouble.

It has already been pointed out that the continual motion of the piston to and fro in the cylinder gradually wears away some of the metal of the cylinder liner, leaving a ridge at the end of the travel of the first piston ring. In extreme cases the wear is so pronounced, that the piston becomes quite slack in the liner, and this will sometimes prove to be the cause of the knock. Thus, when the explosive mixture is fired, the force of the explosion causes the piston to shake against the internal surface of the liner, and a knock is thus liable to be heard each explosion stroke. A knock of this character can scarcely be regarded as a serious one, since no undue stresses are likely to set up on any of the parts. What is perhaps of more importance than the knock is the loss which will probably occur by leakage of the explosive mixture past the piston. The remedy for the trouble is, of course, to re-bore the cylinder liner and fit a new piston, or else to fit both a new liner and a new piston.

One cause of knocking in gas engines, but one which is usually easy to discover, is undue clearance between the spindles of the different valves, and the levers which oprate the valves. When the valves are properly adjusted for lift, they are first opened very gradually by the cams which work the levers, and then more rapidly. When, however, there is a considerable amount of clearance between the valve spindles and the levers, the latter, instead of coming into contact at a moment when they are moving very slowly, only do so when the rate of motion has become comparatively great. The result is that the levers, instead of coming into gradual contact with the spindles, bang against them, thus tending to cause a knock. If now the valves lift easily, the force of the blow is relieved, and the knock will be of little importance, but if, on the other hand, much force is required to lift the valves, the knock is liable to become somewhat severe. In the case of the gas and air valves, comparatively little force is required to open the valves, because each valve opens at the commencement of the suction stroke, when the piston is really reducing the pressure against which the valves have to lift, and so assisting in opening them.

Now the case is quite different with the exhaust valve. This valve has to open at the end of the explosion stroke, when the pressure in the cylinder is considerable. Since, in addition to this pressure, the pressure of the spring which keeps the valve down on its seat during the admission, compression and explosion strokes have also to be overcome, not to speak of the weight of the valve itself, it is not difficult to understand that the force required to open the valve is considerable. Hence, when there is much clearance between the exhaust valve spindle and lever, the knock resulting may prove to be somewhat serious. The force of the blow is, of course, transmitted to the teeth of the skew wheels, which drive the cam shaft and if these teeth are much worn, as they frequently are in engines which have seen much service, risk of breakage of the teeth is incurred. Knocking of a somewhat similar nature to the above will sometimes occur as the result of undue wear of the rollers, against which the cams work, the latter banging against the rollers once each cycle. Indeed, in old engines, where all the cams have become badly worn, the working of theh engine has, in consequence, sounded like the rattling of a basket of pots.

Another somewhat common cause of knocking in gas engines, is early firing of the explosive mixture. Thus, if the charge is fired much before the piston reaches the end of the compression stroke, the general effect is to tend to check suddenly the motion of the piston, so that if there is the slightest lost motion in the moving parts, a more or less severe knock is liable to occur each cycle.

Too early firing may of course be caused through improper adjustment of the ignition arrangements, but it will sometimes occur when the adjustment is quite in order. The trouble will then generally be due to the deposit of carbon on the valves, the cylinder end, and on theh piston.

When the trouble referred to is experienced, it is therefore well to look for evidences of carbon deposit, and should any be discovered, it should be removed at theh earliest opportunity. Satisfactory removal can, as a rule, only be effected after the piston has been withdrawn. It is far from wise merely to loosen the deposit and trust to this being blown out through the exhaust valve. Unless the deposit is positively removed by hand after the piston has been withdrawn, there is every probability that the engine will soon suffer severely from scored piston rings and cylinder walls.

TURNING MARINE THRUST SHAFT

One of the most important parts of a marine engine is the thrust shaft, which transmits the whole thrust of the propeller to the hull, through the medium of the thrust block. It has also to transmit the power from the engine to the propeller, therefore being also subject to torsion. The collars on the thrust shaft have to be turned and faced accurately to ensure an even bearing on all the surface of the thrust shoes. The illustration shows a 13¼ inch diameter, thrust shaft for a large steamer, on the lathe. The engines for which this shaft was built are triple expansion, 25 inch by 42 inch by 67 inch by 42 inch stroke. The flanges of the thrust shaft are 25 inches diameter, collars 22 inches diameter, and the total weight 7,000 lbs. The tail end shaft and all the intermediate shaft lengths were turned up on this lathe, which is the 42 inch triple geared engine lathe of the Canada Machinery Corporation. This lathe has been designed expressly for machining heavy pieces such as described above, and is made especially strong to carry the great weights involved. The bed is made very deep and braced with cross ribs of box design. The headstock is made proportionally strong with the base, and is provided with a four step cone, and back geared drive, in addition to a triple geared drive direct to face plate. The cone has extra wide faces to enable a wide belt to be used, this giving greater power than usually obtainable in this class of lathe. The changes of feed are obtainable through the feed box on the bed below the headstock, and by changing the gears on the head and quadrant plate, any desired feed is obtained. The lathe in the illustration is fitted for motor drive.

Washington.—Ships carrying 200,000 tons of food for the populations of France, Belgium and Austria are now en route to Europe, proceeding under sealed orders to Gibraltar and Bristol Channel ports. They were sent on Mr. Hoover's orders.

New York.—The impending deal, by which 100 ships owned by the Mercantile Marine Company would pass to a British syndicate, has been suspended by request of the authorities at Washington. Directors of the company will meet again this week, when it is expected definite information from Washington will be forthcoming.

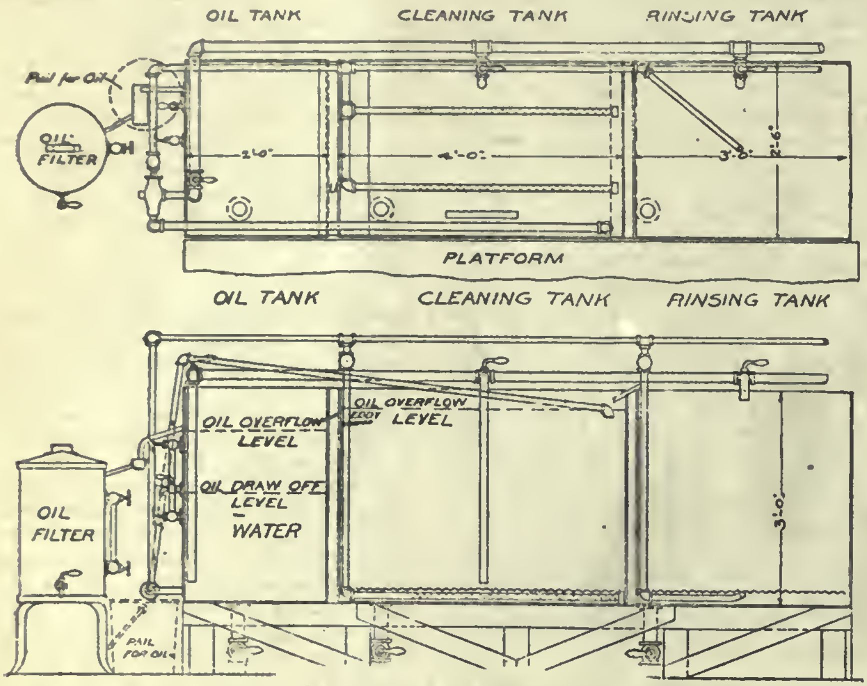
SALARIED MEN

The tendency of modern business is to favor payment by results, for there are few branches of work in which such payment, where it can be applied, does not yield increased output and earnings. Even before the war some industries could not prosper without it, and after the war, few will be able to survive that do not adopt it. Methods of payment by results are naturally easiest to devise for men engaged on direct production, whose individual work can be directly measured. They are less easy to arrange, though not impossible or unusual, for the much smaller class of men who have the entire control of some separate manufacture. But between these two extremes there are large numbers of men whose work, though it is indispensable to production, cannot be identified or measured separately. They included some of the most valuable workers, whose skill may often require an education as well as ability much beyond that of those who are paid by results. For the efficiency of an industry to be maintained, or advanced, the right men must be attracted into this class of work, and, in order that they may be, their reward must be made attractive. There is too much reason to believe that salaried men as a class are paid less than they would get if the actual value of their work could be measured, particularly those in posts that receive the medium or lower salaries. The draughtsman, the works engineer, the works chemist are usually keen on their work and do their best; but this is not sufficient if the best men are not attracted, nor can underpaid men of ability, however good their intentions, do as well when engaged on work that is not paying them fairly, as they could with the encouragement and stimulus of proper remuneration. The standards of salaries paid for this class of work will determine the class of lads who will look to it for their careers; and the engineering trades might well consider whether these standards are as attractive as would be reasonably prudent.—M. E.

TURNING THRUST SHAFT FOR MARINE ENGINE

THE RECLAIMING OF COTTON WASTE

NEW cotton waste costs from eleven to fourteen cents a pound. It can be recleaned by a simple process for less than a cent a pound.



LARGE TANK WASHING OUTFIT

For many years it was quite a common practice to use, for fuel waste and wiping, cloths which had been used about power plants and machine shops for wiping purposes. A cheap and simple method has been worked out whereby waste and rags can be recleaned at an average cost of three-quarters of a cent a pound. The process in use in a large number of plants for several years is very simple and on account of the low cost is finding increasing favor among not only manufacturers, but power plants, printing establishments, railroads, and all branches of industry where waste and cloths are used.

One of the main advantages of this process is that the waste or cloths are in better condition after washing than when new, as the washing does not injure the fiber, but makes the waste or cloth softer and consequently more absorbent. Waste or rags cleaned by this method can be recleaned from one hundred to one hundred and fifty times, or until the material is worn out.

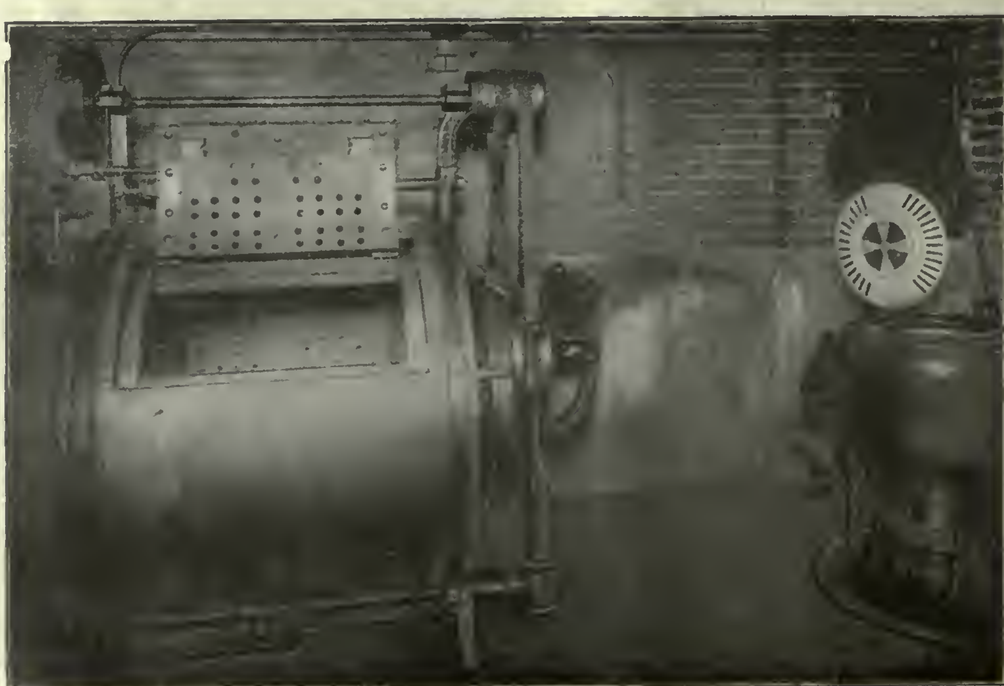
Oakite, the product which does this work so effectively, is a dry white powder—a combination of mineral salts which dissolves readily in water. It contains no acid, sal soda, potash, or lye, or other substances which are injurious to the most delicate fabrics or the human skin. Oakite cleans on an entirely new principle. It emulsifies oil and greases—breaks them into finely divided particles, thus destroying their adhesive nature. This is a purely physical action. The action of old time alkali cleaners is chemical. They saponify oils and greases, combine with them and are thus rapidly used up. Only a small amount of oakite is necessary to emulsify a large amount of oil or grease.

The process is as practical for a man who washes a few pounds of cloths or waste a month, as for the plant which washes a ton a day. For a small plant the only equipment necessary is a barrel or tank with a steam pipe or coil. About twenty-five gallons of warm water is run into the tank and two pounds of oakite is dissolved in the water. About forty pounds of material to be cleaned is placed in the tank and the water boiled for fifteen minutes. This liberates the oil, which rises to the surface of the water and may be reclaimed by filling the tank with water until the oil runs out of the overflow. When no more oil escapes from the waste, the washed material is rinsed in a separate tank, and after drying is fit for use again. The character of the oil is not affected by oakite and it can be reclaimed and used again.

For concerns washing two or three hundred pounds of waste or cloth at one time, or twelve pounds a day with one man operating, the equipment consists of a large tank built with three compartments—one for washing, one for rinsing, and one for the overflow of oil and water. Have the washing compartment in the middle. This should be equipped with water and live steam connections. A centrifugal dryer is convenient and effective. An oil filter may be used with good results for reclaiming oil. A diagram herewith shows the details of a serviceable equipment for washing waste or cloths and filtering the oil.

A laundry wheel or similar equipment can be used.

A booklet containing diagrams of tanks and outlines of formulas and methods suited to all conditions for cleaning waste and wiping cloths will be furnished on request by the Oakley Chemical Company, 22 Thames street,



WASHING WIPING CLOTHS WITH OAKITE—LAUNDRY WHEEL METHOD—36" x 39" STANDARD LAUNDRY WHEEL ON LEFT; 22" CENTRIFUGAL WRINGER ON RIGHT.

WELDING AND CUTTING

The Electric Arc Used in Steamship Overhauling

Westinghouse Arc Welder Does Good Work in This Line—Repairing a Furnace While Under Steam—Variety of Work Carried On

THE all-round usefulness and adaptability of the electric arc method of welding is well exemplified by the work carried out at the repair shops of the Canada Steamship Lines, at the foot of Yonge Street, Toronto. The machine, which is a Westinghouse arc welder, using direct current of 150 amperes at 75 volts, was installed in 1915, and was one of the first machines to be imported into Canada. The machine shop was started at the same time and has grown into a well fitted up repair shop, where practically all the repairs necessary for the company's steamers can be carried out with ease. The shop and welding outfit are under the supervision of Mr. Noonan, the superintendent engineer of the company, and some very interesting repairs have been performed under his direction. The welding metal used is a soft Swedish iron wire known as Premier welding wire, and during the years of the war, this, like most other steel material, has been hard to get, but since the armistice has been signed Mr. Noonan has been notified by the Steel Company of Canada, who supply this wire, that they can now fill his orders. Last winter no fewer than twenty steamers were laid up at Toronto, and the repairs made at the company's shop, so that there is no lack of work for the machine shop or the welding apparatus; in fact, a welder and helper are kept steadily at work all the year round, and in the summer season, when the boats are all working under conditions of rush, the welding outfit makes possible quick repairs, and eliminates delays. As an instance of this, an especially interesting case might be mentioned. One of the steamers came into port with a furnace leaking, and it was feared that she would be subject to considerable delay. In the ordinary course of events she would have been delayed quite a bit. The cause of the leak was a crack in the furnace tube, and the usual way of repairing this would be to drop the pressure off the boiler and repair the crack by either plug stitching or a patch, according to the condition of the furnace. However, it was decided to repair the furnace by the electric welder, and furthermore, to do it without waiting to lower the steam pressure. This was a bold policy, but such was the confidence felt in the process that no hesitation was expressed by anyone connected with the job. The vessel was brought round to wharf where the machine is installed, and the cable led aboard. The boiler was carrying 125 pounds of steam per square inch, and the job was done with this pressure on. The first difficulty was to stop the water leaking through the crack, and by deft manipulation of the electrode, a thin skin was worked over till the leak was stopped and then the weld was built up in the usual manner. That job held tight all the rest of the season, and was found to be perfectly good when the vessel was laid up at the end of the summer.

Another case was that of a boiler which had undergone extensive repairs, having new combustion chamber back sheets fitted and necessarily new combustion chamber stay bolts. The repairs being completed, the boiler was put under hydraulic test, and at 125 lbs. pressure per square inch, a leak developed in the back head near the ring seam. It was decided to call in the services of the welding machine once more, and the repair was made in practically the same manner as the repair on the furnace. The first thing to do was to stop the water leaking through the crack, and once this was accomplished, the weld was built up to the required strength. This job was also perfectly successful, no further trouble being experienced. For this kind of work there is no doubt the arc welding is superior to the oxyacetylene flame in the opinion of the men who have these jobs to do, and there is no doubt that the feature the electric arc pos-

WELDING REPAIR TO MARINE BOILER

sesses of applying the heat right at the job itself, and localizing it, has a great advantage over the much larger surface affected by the oxy-acetylene flame. The usual method of repairing a crack or leak is to V the bad spot out so that it can be rebuilt with new metal. If the part is very bad or covers a large area, the piece can be cut out completely and a new piece fitted in. New nuts have been formed on the end of combustion chamber stays by the building-up process, and stay tubes stiffened at the end where corrosion has taken place. Paddle wheel arms are welded in place, badly scored piston rods have been filled in and then turned up as good as new, and many other varieties of repairs are performed daily.

The subjects of our illustrations are repairs on circumferential seams of boilers in one of the company's steamers. The first illustration shows the welder closing up a leaky seam at the forward end of the boiler, close to the floor plates a job which is one of the most awkward to be done by hand caulking. The other illustration shows a completed repair on the circumferential seam at the after end of the boiler, at a part where the marine boiler is peculiarly liable to corrosion. This is on account of wet ashes lying against the shell during the periods of cleaning fires, and at other times, and also to the effect of leaking gaskets on the manhole door, the water running down and along the seam. This seam also is liable to leaks due to the unequal expansion of the boiler shell when raising steam, and even when working. It is not unusual in a boiler which has not been properly circulated, to find this part of the shell and head comparatively cool long after the pressure has been raised to the working point.

SWITCHBOARD

We are indebted to the courtesy of Mr. Noonan for the opportunity to obtain these illustrations, and the information furnished by him.

A NEW PRINCIPLE IN WELDING AND CUTTING APPARATUS

The Bastian Blessing Co. have recently issued a new pamphlet descriptive of some of the interesting features and design of their cutting and welding apparatus. Owing to a new principle introduced in the construction of their torches they have eliminated all flashing back and have succeeded in making their torches operate on very low combined pressures. This results in increased production, as it is well known that the flashback is one of the greatest time-wasters in the oxy-acetylene process.

In the operation of the Rego torch equal volumes of both gases are used, this condition being necessary to produce a neutral flame. With the acetylene under a slightly higher pressure that no more oxygen can come through the flame than is necessary to burn the acetylene, thus the flame at no time can become oxidizing in character, and all burning of the weld is completely eliminated.

NEW ANTHRACITE PRICE

Inquiry at the office of the Fuel Controller as to new prices on anthracite, coal elicited the following information: The price charged for anthracite coal in Canada is based upon the prices in the United States, and these are fixed by the U.S. Fuel Administration. In an official despatch from Washington an increase of $1.05 per ton is authorized on domestic sizes, the revision being made to meet increased labor costs. Emphasis is, however, placed in the fact that the new price schedule is effective only on coal mined on or after November 1. Dealers in the United States have been advised by the Fuel Administration that the increased price applies only on coal shipped and delivered after November 1 upon the production of which there has been paid the increase in the scale of wages to the miners. Dealers in Canada should govern themselves accordingly. It is suggested that consumers who are in doubt as to proper billing for coal should refer the matter to the local fuel commissioner.

ACID FOR FERTILIZERS

U. S. War Chemical Plants Will be Used in Producing Crop Coaxers

Before the Toronto section of the Society of Chemical Industry, Prof. J. Watson Bain delivered a lecture on "The Canadian War Mission at Washington and Canadian Industry." Prof. Bain gave up his work at the Toronto University to become technical adviser to the mission.

He dealt with what should be done with the huge plants built for preparing chemicals used in explosives, and stated that a great part of it would ce used in the preparation of acid phosphates to be used as fertilizers, which were needed in great quantities in Canada. He dealt with the fixation of atmospheric nitrogen and stated that cyanamide was already being produced in Canada, but with the plentiful supply of cheap power it would be possible, by several methods, to successfully extract nitrogen from the air. Another application of the power could be made in the manufacture of ferro-alloys used in the manufacture of steels.

He described the enormous scale on which the Americans had been manufacturing poisonous gases, and stated that, had the war continued, the Huns would have had their own medicine back in unprecedented quantities.

A new and very valuable copper ore has been discovered in the district of Varmland, Sweden. It is said to be an oxidized copper mineral consisting of about 90 per cent. pure copper and a small quantity of gold. The mining will probably soon be commenced.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

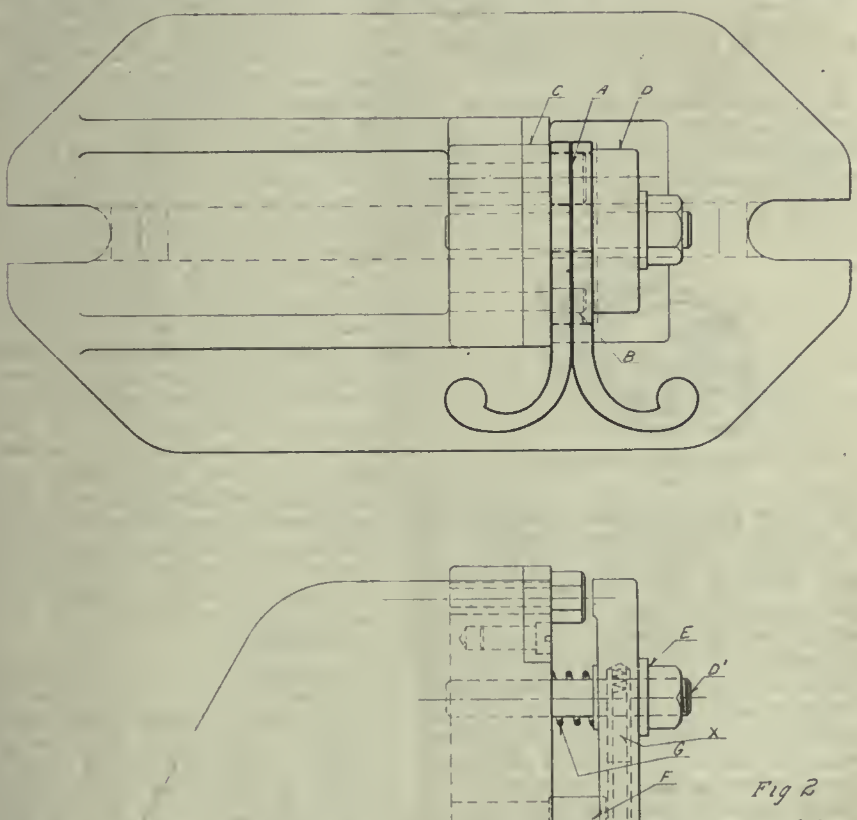
A FORM MILLING JOB ON TWO PARTS

By H. M.

FORM milling, such as is very often resorted to on parts of irregular form, is seldom done to better advantage than is illustrated in Fig. 2 of this article. The work to be operated upon upon is shown in Fig. 1, which is flat on both sides, has curved end and is shaped similar on both edges. This part has a round hole in it and a rectangular slot.

In milling the edges on this part advantage is token of the round hole and the rectangular slot for locating. By referring to Fig. 2 it will be seen that a pin A fits in the hole of the two parts and that the tails on the two parts stand out in opposite directions as is obvious from the illustration. In the rectangular slot of both pieces the pin B is placed. These locate the work the correct height from the table of the machine and radially about the round hole as a center. The two parts are next clamped against the steel plate C by the clamp D, a nut and washer E on the stud D being used for this purpose. Under the tail of this clamp a pin F is used, while the spring G pushes the clamp away from the work when it is released to remove the same. In order to remove the work this clamp is pushed down and it is held down while another part is being put in place. After the work is put in place the two spring pins H push the clamp up until the slot at X comes against the screw, following which the work is clamped as described. The cast iron base, with the tongues to fit the groove in the milling machine table, completes this fixture.

The most interesting part of this fixture apart from the clamping arrangement is that the milling machine cutter forms one-half of the work, including the radius Z up to J on the right hand edge of one part and the left hand edge of the other, and by reversing the position of the two parts the opposite edges are formed, thus one cut on two parts finishes one complete at each setting. Two fixtures were used for machining



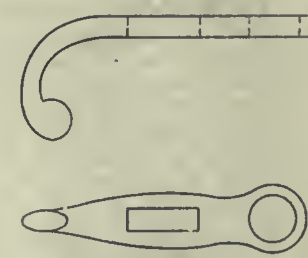


Fig 1.

FIG. 2—PLAN AND ELEVATION OF JIG.

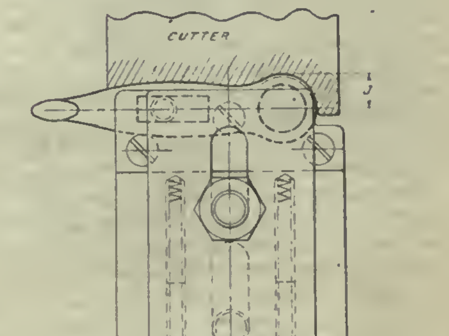

FIG. 3 END ELEVATION

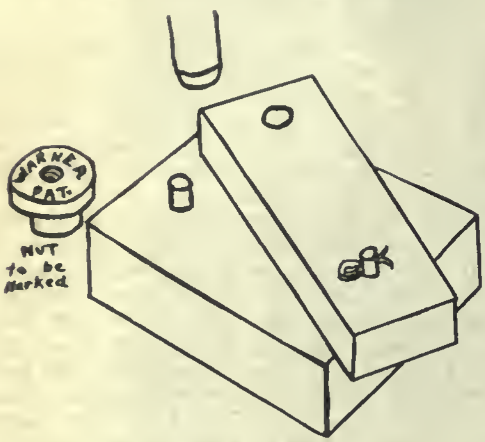
these parts, one being loaded while the cutter was milling the parts in the other fixture.

MARKING BRASS NUTS

By D. A. H.

There were about ten thousand round brass nuts to be marked with the company name. See the figure. A hole was drilled in a piece of steel and a boy set to work to mark them with a hand stamp and hammer. It was an unimportant sort of a job and we were glad to give the boy something that would keep him going for a couple of days. But one of the men willed otherwise.



MARKING BRASS NUTS

He asked permission to spend two hours in rigging up the job to "do it five times as fas on the No. 18 Bliss"—and permission was granted.

In the figure the base is a piece of cast iron picked up and the pivoted piece is a length of cold drawn steel. This latter turns about the pin held in by cotters above and below and rests against a stop pin when the hole (with the nut dropped in it) is under the center of the press. By means of a bushing, the hand stamp was held in the ram of the machine; this dispensed with the use of a hammer entirely and left the boy with nothing to handle but the nuts.

Along with ease of loading, a safety feature was obtained that is worthy of notice. The piece of steel is swung around toward the operator for loading and unloading; after it is filled it is swung back against the stop pin by the simple operation of moving the short end of the piece. This keeps the hands at all times several inches away from the danger zone and the extra movement takes no more time than would be required in placing and replacing the nuts in the more awkward and farther-away hole if it had been made stationary in line with the blow.

OLD-FASHIONED PAINT REMOVERS

The following recipes for alkaline paint removers are of the old-fashioned type; the modern quick process paint and varnish removers, while doing this work very well, and indispensable for refinishing wood in the natural, are entirely too high a price for use in removing paint on surfaces to be painted over. The recipes are as follows:

Dissolve 40 lb. caustic soda, 98 per cent., in 5 gallons of water. Take 8 lb. fine whiting and 4 lb. corn starch, and mix with 1 gal. of the caustic solution to form a paste; apply with an old brush, and leave the paint on for about twenty to thirty minutes. When the paint has softened, wash off with water, using a scraper where required. Will also remove varnish.

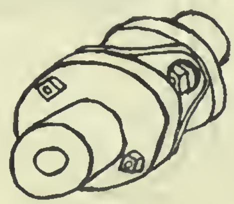
Another very good formula is: Mix 7 lb. of caustic soda, 98 per cent., with 15 lb. warm water; mix 1 lb. corn starch and 11 lb. china clay with 1½ gallons of water, adding to it the caustic soda solution, forming a paste that must be beaten until free of lumps. Apply freely to the surface with an old brush and permit it to remain until the paint or varnish has lifted, then scrape and wash off with warm water. Wall paper can also be removed in this manner, when the remover is further diluted with water. For cleaning painted surfaces, use a weak solution of the remover.

Operators, whose hands are easily affected by strong lye or soda solutions, should wear rubber gloves while working with the remover. In order to neutralize the alkaline nature of the remover a small portion of vinegar can be added to the water used for cleaning off, say 1 gill to each gallon of water.—M. M.

LEATHER FLEXIBLE COUPLINGS

By D. A. MIDDLETON

The use of leather couplings has increased surprisingly in the last few years. The self aligning feature, their moderate cost, the ease of installation—all have contributed to their popularity.



FLEXIBLE COUPLING

Up at the gas works they had a couple of turbine-driven blowers that had always given trouble with the bearings. They wouldn't have anyone but us do their repair work and we diagnosed the trouble as misalignment between the two units of a set; we wanted to put in leather couplings, but the management was staid and refused, and after we refused to do any more work on the machines as they were, they let them run, leaking and heating and pounding.

One Sunday morning Smith, the superintendent, called up at six o'clock, said something had to be done, they couldn't get the gauge up to sixteen the night before and it ought to have stood twenty. All this I had anticipated and had had a coupling made up and waiting. The drawing shows this and the simplicity of a leather coupling for driving shafts. Well, Smith consented to having the rigid coupling taken out if we would run new bearings and get the unit in shape for night. So, accordingly, this was done that Sunday (as it had been done before with little results) and the leather coupling put in. In the two years since there has been no heating with those bearings and the gauge stands up to twenty all the time. Final proof is found in the order Smith just gave us to so equip the other machine.

THE EFFICIENCY MERCHANT

By A. L. Haas

The purveying of efficiency in the shape of so much confidential talk, and the installation of some card index system at inclusive rates for such service, is a matter quite easy to ridicule. Indeed, efficiency cannot be so retailed.

Like success, efficiency cannot be handed down ready made, similarly to reach-me-downs or packeted sundries, and all the advice in the world is fruitless failing the right spirit to effort. Like political catch cries, or newspaper shibboleths, certain ready-made phrases easily coined have an hypnotic influence and are currently popular.

Efficiency in any trade or business cannot be captured by the aid of a casual stranger, unused in the particular line.

Even scientific management is the result of much diligent application of experience, knowledge and commonsense to particular problems of industry. Although an organizing genius (few exist) can show results after patient disentanglement of current problems, it is impossible to transfer system unchanged from one location to another.

Efficiency research means the application of a dispassionate and unprejudiced intelligence to simple problems in sequence, using patience, tact, and discrimination (this last is of importance) for the purpose. The present aim of efficiency propaganda is to raise the commonplace and average to somewhere near the exceptional, by pre-vision and stimulation. Catch cries are useless without definite planning and good staff work. Some of the literature of the movement leads the reader to suppose that scientific management has discovered afresh the cardinal virtues, actually its process is as old as Eve, it asks why? and when the answer is insufficient or unconvincing it investigates and provides a new solution.

The alleged specialist who hawks round empirical specifics is most often unable to land results unless conditions are identical; in actuality they never are similar. Absurdities abound in the spellbinding of the orator who, utilizing industrial phrases, weds the methods of the revival preacher and the electoral platform to achieve an evanescent effect.

Efficiency cannot be achieved save by the ancient method of diligent application, hard work, and definite and specific hard thinking. The only merit in the outsider is his unbiased viewpoint; it is some asset towards fresh conception; ignorance in this wise may be useful, since tradition does not bind his feet nor enchain his understanding, otherwise the peculiar virtue of the specialist efficiency merchant seems a type of mental alertness, some smooth phrases, and a bewildered proprietor; this occurs often enough to warrant notice. Efficiency is relative; its practitioners were not unknown before the advent of the stunt performer.

Predisposition is the greatest single item affecting the human change, persuaded is half way to alteration, and the hope of present propaganda and publicity is that curiosity re-aroused will serve to invoke the general spirit which strives, not so much toward repentance as to fresh conception.

It is the mind reluctant to accept existing conclusions as ultimate, and willing to experiment undaunted by partial failure, who is likely to reach tangible results. The efficiency merchant has performed one useful purpose, he has aroused curiosity, stimulated desire, but has not provided and cannot provide a panacea; the solution in each case has to be wrought out by toil, the application of tough mentality, and can be reached by the determined without vicarious aid.

Men past the first flush of youth shrink often from the unusual because it is strange. Efficiency is to be won, not bought, and its price is an unremitting vigilance and flexibility of mind; moreover, there are not enough efficiency merchants to go round; one should be permanently stationed in each works, and it is best that he be the responsible man—whether director, proprietor, or manager. Without bluff or brag there are many such, and it is noticeable that the external investigator avoids some industries altogether; he would be out of breath long before he began to catch up with those vitally interested, who are responsible.

RETURNED SOLDIERS SHOULD BE PROTECTED FROM FRAUD GAMES

Editor CANADIAN MACHINERY:—

The name "Returned Soldier" is in danger of becoming very much wronged. We have all the sympathy possible for the returned men, and are willing to do all we can to help them regain a footing in civil life.

But there are cases where men have played on this fact, perhaps to their own advantage, but to the disadvantage of the returned soldiers as a whole. And, furthermore, there are cases where men have actually claimed to be returned men, and have played on people's sympathies and purses, when they have never been out of Canada, and have never even tried to enlist.

Such a case as this came to light a few days ago when a man who was canvassing subscriptions for one of the Toronto daily papers claimed to be a returned soldier, and in proof showed a hand with the fingers badly mutilated. However, no returned button was in sight. And when questioned on this point he said that this returned soldier business was being done to death and the best thing a man could do with his button was to leave it in the pincushion on his dresser.

On making inquiry at the newspaper office where he was employed, it was found out that the man had never had a uniform on, and had had his hand mutilated in some factory.

We are all ready and willing to help the returned man when he needs our assistance, or even to help this man with his maimed hand. But when a man, be he returned soldier or civilian, claims he is making "about five dollars a day," it does not seem fair that either one should play on his infirmities to elicit the sympathy of the public.

We want to help the soldier. But we think it only fair that he should help himself. He shouldn't whine about being a returned man. He should be glad of it. Glad he was not buried on the battlefield. Glad to be alive to return to Canada, to live in the peace he has helped create.

All honor to the returned man. He has done his bit. He has heard and heeded the call of King and country. He has helped to make the world safe for democracy. But don't let it be possible for a few returned men, and a few despicable cowards who claim to be returned men, to spoil that glorious name "A Veteran of the Great War."—READER.

FRICTION FABRICS

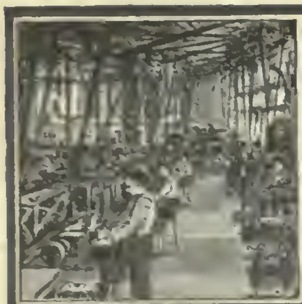
By H. A. L.

The material wherewith to line clutch and brake surfaces has always been a problem. In railway work the cast iron shoes used wear out rapidly, and it is considered more economic to have the metallic wastage upon the easily-renewed and cheaply-produced brake shoe than on the expensive tire. At the same time the metallic wastage irrecoverable as scrap must be very large. In the motor car the cone clutch largely used has most often a leather lining, while the brakes are steel bands over drums, which serve to give the braking effect when controlled from the dashboard.

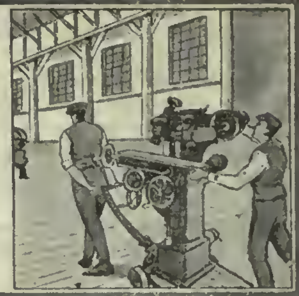
Recent solutions of the problem have led to the marketing of textile fabrics of special type for which large claims are made. One of these materials seems to have disappeared, but the other is rather prominent.

Both claimed an asbestos foundation, and are supplied in a form resembling belting or braid of very coarse texture. As in the case of engine packing, the experienced engineer is always somewhat curious and sceptical, and while no doubt is cast upon the efficacy of the materials the result of a close examination is interesting. At first sight the resemblance to what is known as wire woven, high-pressure packing is considerable, the chief feature of the construction seems to be the combination of a single brass wire of fine gauge as the core of a rather coarse textile thread. High pressure packing is similar in construction, the asbestos fibre being rolled or carded on to a wire core. This reinforced or composite thread is then woven into the familiar forms.

In the case of the material discussed, the claim as to the inclusion of asbestos seems hardly warranted, for the thread seems to consist of a large proportion of fibre other than asbestos. It was claimed at one time that old sail canvas made the best canvas engine packing, universally known as Tuck's, the stretch having been taken out of the fabric by prior use. At the same time such material is initially cheaper, and the economic factor would probably be a greater incentive than the reason alleged. However this may be, in the friction lining similar material seems indicated, the fibre looks more like old rope, either hemp or manila. It has occurred to the writer that the inclusion of asbestos is to minimize overheating in the absorption of power by friction. The rope used in the Prony brake does occasionally smoke, but not usually, unless its proportions are inefficient and it is grease saturated, when its liability to overheat is similar to that of oily waste. The presentation of a wire mesh surface by wear in conjunction with a textile material of frictional qualities finds a precedent in the non-slip stair tread, where lead and steel or cast iron form a composite surface, the harder material, whether as straight lines or woven wire diminishing wear while allowing the softer metal to exercise its non-slipping qualities. Lead in this particular is the safest material known, even when greasy, or otherwise rendered in a condition where other metals would provoke accident. The tendency to slip on greasy M. S. chequer plates is very pronounced. Asbestos being immune from any tendency to fire, and since it can be procured wire-woven it is a little surprising that the ordinary commercial material used everywhere for engine packing should be unknown as a brake lining. Perhaps it is the initial cost of such high grade packing, but the results of any tests would prove interesting. The material marketed under a trade name is certainly cheaper to produce so far as a detailed examination would show, but if engine packing of the type indicated serves the same purpose this should exert a salutary check upon any undue price. It certainly seems open to the engine packing maker to heavily adulterate his product with alien fibre of cheaper character and make this up in suitable dimensions. To add to its resistivity some drying oil or resinous substance may also help its friction qualities.



DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

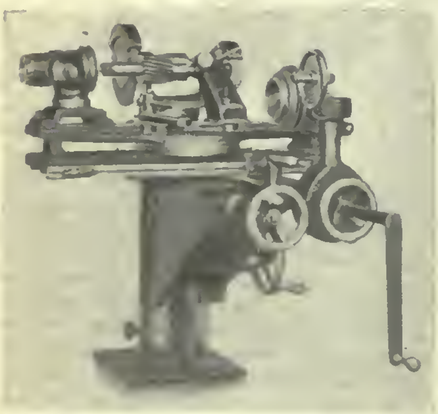
UNIVERSAL TOOL GRINDER

In developing their Sterling Universal tool grinder the McDonough Manufacturing Co., Eau Claire, Wis., have produced a machine which is substantially built and will grind any shape cutter in a satisfactory manner. They are particularly adapted to the grinding of cylindrical internal angular and face work such as counter-bores, face mills, internal gauges, end mills, gear cutters, reamers, jig bushes, flat surfaces and formed cutters.

All slides are machined and hand scraped to surfaces, plates and straight edges, giving true and flat surfaces with co-operating parts machined and hand scraped to fit perfectly.

Guards for the wheels protect the operator in the event of a wheel bursting. These guards need not be removed in any operation possible, as they do not interfere with the grinding capacity of the wheels. The value of such guards cannot be overestimated.

The base and column are cast in one piece, thus giving greater rigidity to the machine and eliminating any chance of vibration of the knee or table.



UNIVERSAL GRINDER SET UP FOR SHARPENING CUTTERS.

The base is of cabinet construction, heavily ribbed, and has ample space for storing attachments if desired.

The sleeve or outer column which fits over the main column, is of one piece construction with large V knee slides. The sleeve locks rigidly to the column at any desired point by means of hand screws and friction collars. The hand screws are set directly on the gib and instantly lock the sleeve to the column with a half turn.

The wheel spindle is of exceptionally large construction, hardened and ground and accurately fitted in S K F self-aligning double roll ball bearings equipped with dust covers. All adjustments necessary where brass or bronze bearings are used, are eliminated by the use of these bearings. The fact that ball bearings are used makes it possible to use a larger diameter spindle, adding to the stability of the grinder and its ability to take heavy feeds.

The head stock is full universal and is graduated in degrees for vertical or horizontal swivel, and revolves on a removable base clamped to the table T slot. The head-stock is fitted with a taper arbor with provision for driving work on live or dead centers. The tail-stock is spring controlled with current actuating lever lock.

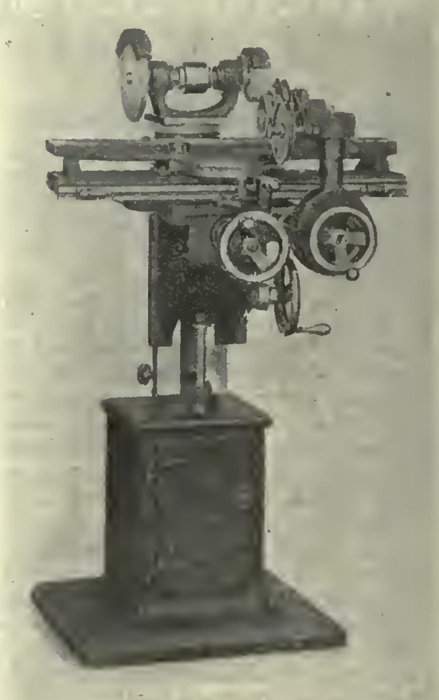
The internal grinding attachment is removably mounted on a flange formed with the spindle bracket and consists of a tool steel spindle fitted to run in two S K F ball bearings. The attachment is clamped on the machine and is driven by belt from an arbor pulley mounted on the wheel spindle.

The transverse movement of the table is actuated by means of a hand wheel located directly in front of the knee. The motion is transferred to the platen table by means of a screw, which functions in a bronze nut fastened to the bottom of the saddle. A micrometer gauge on the screw spindle makes adjustment of the table accurate to the thousandth of an inch.

The longitudinal movement is actuated by a hand wheel located to the right of the saddle through a rack and pinion which is in turn moved through a set of spiral gears. An attachable long crank is supplied for giving a more delicate hand movement for certain reamer work and similar operations.

The automatic power feed attachment makes easier and more rapid work possible. The power feed device is attached in place of the hand table feed, and comprises a reversing mechanism enclosed in an iron case, and a bevel gear transmission to a vertical which in turn carries a grooved cone pulley for driving the feed mechanism. A special feature of this feed is its adaptability for work in any position as the pulley can be lined up with the driving drum regardless of the table position.

The Coppus Engineering and Equipment Co. have issued a new catalogue describing the Coppus Turbo-blower for



UNIVERSAL TOOL GRINDER.

undergrate draft and other industrial purposes. Up till comparatively recent times the chimney was the only practical way to get draft. The limitations and cost of a chimney brought about the use of mechanically operated apparatus. The use of the Coppus turbo-blower as a means of producing forced draft is fully dealt with, and the advantages of this system are explained. The blower consists of a propeller fan driven by a steam turbine, both mounted on the same shaft and located on the boiler front. The mechanical features of the blower are dealt with in detail; the lubricating system, ball bearings, construction of the steam strainer and the arrangement of the exhaust are all shown to good advantage. In a blower turbine driven, the construction of the turbine wheel demands careful design for economy and this construction is clearly developed. An interesting portion of the descriptive matter deals with typical applications to the various types of boilers.

THE ALBANY HIGH-SPEED DRILL

We illustrate herewith a high-speed tool-room drill, which contains several unique features. The makers of this drill, the Albany Hardware Specialty Manufacturing Co., Albany, Wis., claim for some of the advantages, rapidity in starting and stopping the spindle, changing drills and chucks, and changing speed, and also accuracy of drilling to depth. The drill has ten changes of speed, varying from 286 r.p.m. to 2,140

ALBANY HIGH SPEED DRILL

r.p.m. The capacity of the drill is from 0 to ½ inch holes, and to the centre of a 12-inch circle. The height overall is 72 inches. The spindle is driven by a friction wheel, which is driven by a cast iron hemisphere, engaging with a friction wheel on drive shaft. The hemisphere is carried on a pivot, and a lever is fastened to it so as to enable it to be moved in relation to the two friction wheels, thus varying the speed of the spindle. An index is provided on the lever quadrant. If the lever is pulled down to the lowest notch, the friction wheel on driving shaft will be running on the largest diameter of the cast iron hemisphere, while the friction wheel on spindle will be driven by the smallest part of the hemisphere's periphery. This combination will give the lowest speed, 286 r.p.m. The drive shaft is carried on radial ball bearings of the silent type, as is also the friction wheel. A positive depth stop is provided for duplicate drilling, so arranged that it does not lessen the spindle travel when not in use. The spindle has a vertical travel of 4½ inches and is finished with a micrometer depth gauge, graduated in English measure on one side, and metric measure on the other. It can be turned over to either side as required. A very complete description of the details is contained in a catalogue issued by the makers, which will be of interest to users of this type of tool.

WOMEN NAVAL ARCHITECTS

The entrance of women into many scientific activities has shown itself from time to time in an earnest desire to be given a status in the particular activity in which they have qualified themselves to become useful members. It is certainly a sign of the times when the Council of the Institution of Naval Architects is seeking to obtain the views of the various classes of members of the Institution on the subject of the admission of women to such class or classes of membership as they may, apart from the question of sex, be qualified for under the present rules of the institution. At the present time, women are not eligible under the existing rules covering the admission of candidates, and it is therefore necessary to alter such rules, which requires the assent of a two-thirds majority, and if this is obtained, the consent of the privy council to the corresponding alteration in the Royal Charter of Incorporation would have to be also obtained. It is understood that at the present moment there are only three ladies seeking admission into the institution, each of whom has received a technical training, and has been engaged in making calculations or carrying out experimental work connected with shipbuilding. One of these ladies is the joint author with a member of the institution, of a paper contributed to the present year's transactions, viz., "The effect of the longitudinal motion of a ship on its statical transverse stability," by Mr. G. S. Baker, O.B.E., and Miss E. M. Keary, and was read recently. If women are admitted they will only be admitted on the same qualifications which apply to the opposite sex.

RUST-PREVENTING VARNISH

Resin six parts, sandarac nine parts, gumlac three parts, turpentine six parts, and rectified alcohol nine parts. The resin, sandarac, and gumlac should be mixed together in a pounded condition and then carefully heated until melted. When they are well melted the turpentine should be added very gradually, stirring all the while. The mixture should then be digested until dissolution takes place. Then add rectified alcohol up to the amount stated above. It should afterwards be filtered through a fine cloth or thick filter paper, and preserved in well stoppered bottles so that no evaporation can take place.

SUGGESTION FROM WEST

A proposal that Alberta and Saskatchewan deposits of low-grade coal, which will not stand shipment by reason of its friability, be utilized for the generation of electricity for light and power, has been made to the Advisory Council for Industrial and Scientific Research by Hon. C. A. Dunning, provincial treasurer of Saskatchewan. The suggestion is that power houses be erected at the mine fields and the current be distributed to farmers and other consumers. The proposition has been referred to the council's lignite committee for investigation.

NICKEL PLATING BY RAPID PROCESS

Rapid plating is the rule in America. The common practice is to work at 10 to 20 amperes per square foot, using concentrated solutions, but this has been improved upon. It was found that high-grade commercial cobalt plating could be achieved in three minutes when working at 150 amps. per square foot, and a solution of 312 grammes of anhydrous cobalt sulphate per litre. The same practice was then applied to nickel plating, but it was found that the generation of acid cut down efficiency and produced hydrogen at the cathode. This difficulty has been overcome by adding a small quantity of chloride and heating the solution. This done, a 25-gallon nickel cast can be worked at 125 to 150 amperes per square foot, producing heavy, durable deposit in five minutes.

DRIVING BELT OF IRON WIRE

The shortage of leather and textile fibres suitable for making up into driving belts, has produced a new industry in Austria, which may be worth while noting. These belts are now made of iron wire in some instances in combination with paper twine. The standard type consists of double iron wire, spirally twisted together, and in part slightly copper-plated by a chemical process. They range up to about 10 cm. broad. Another sample is of wire gauze strips interlaced with one-ply and two-ply paper yarn, partly with single and partly with double threads. It is bound at the edges with paper yarn, then strongly impregnated with tar asphalt, and flattened out between rollers. A third sample is bound with iron wire spirally twisted.

Leadership Needed Now

THERE are a number of organized bodies in Canada that have been making munitions. They have good organizations, good executives and good premises, and a certain amount of good machinery adaptable for any line of work.

The business of making necessary changes in the plant, of discarding the single purpose machinery and putting in other special machines, is not worrying them. They would do it in a minute if they were certain which way to turn. Many of these firms had no special lines before the war. Others had.

"What shall we make?" That is the question that is being asked, perhaps not openly, but certainly in the quiet of business councils, and it is the largest matters that is up for consideration just now.

It is a case in which individual initiative should be backed up by some central encouragement and control to prevent over-production along certain lines that may already be fairly well established here, and along others for which the market may yet be uncertain and problematical.

Well, What's the Use?

WHEN it comes to stating the case correctly the medal for this week goes to the scrap metal dealer, who stated to CANADIAN MACHINERY:—

> "What's the use of putting a price on stuff that you don't want to buy, and what's the sense in naming a figure when no person wants to buy what you've got to sell?"

It's much more interesting to have a man stick his thumbs in the place where sleeves should grow in a vest and size up the situation that way, than to have him look sideways from his desk and moan "Nothin' doing."

Canada is the second largest pulp and paper producing country in the world, and is rapidly overtaking the United States, which holds first place.

Some of the women who have been working around machine shops for the last three or four years will now be running the egg-beater by a contrivance hitched to the electric toaster, and washing dishes with the same foot power that runs the sewing machine.

The Industrial Slacker

A NEW post-war phrase is being developed in this country. It's not particularly choice, and it's not one that a person would go out of his path to claim.

The phrase is "industrial slacker."

When the voluntary plan of enlistment was in force in Canada, the word "slacker" came to the surface. It meant a person who was standing back and allowing others to fight for him—one who was getting from under his responsibility.

That slacker person had a rather serious time of it. He couldn't stand back and say "This war is no business of mine. I'll stand back and wash my hands of the whole affair."

And bear in mind there was much at stake. Public opinion wasn't forcing the military slacker to a southern summer resort. It wasn't asking him to go to a circus.

Rather was public opinion putting on the screws that ultimately would put that man in the stern path of duty. He risked everything—life, health, position, home. That's the path that public opinion mapped out for the military slacker.

Now, then, where does the industrial slacker come in?

The industrial slacker is the man or the company that is closing up its factory now and tossing its hundreds and thousands upon an unprepared labor market because it fears that some of its war profits will be lost by operating in doubtful circumstances in regard to present costs and future market.

The industrial slacker is the nation or the government that tells its returned men that their jobs have gone by the boards, while they were getting shot at to save the carpet-slipper moneymakers at home.

The industrial slacker is being urged to do his part as the military slacker was urged to do his. He is being asked only to risk dollars, while the military slacker was urged and hounded to risk all—dollars, life, limb—everything. The risk of the man who put on the uniform was a thousand times greater than the risk of the man who is asked now—to the Government that is asked now—to risk its dollars in order that this country shall get a footing on its after-war trade.

The Canadian Government should stand behind Canadian industry for the time. The Government helped to turn peace lines into a war machine, and it should participate in the process of bringing them back again to a peace basis.

The Canadian Government does not need to be stingy in the matter. Neither do many Canadian firms. In both cases they have money to back them up in any move they make.

Reconstruction doesn't consist of firing a thousand hands in a day; it doesn't consist in squabbles at Ottawa regarding which faction there won the war; nor does it consist in telling returned men that, having taken off the uniform, we have no further work for them to do.

Canada calls for men to be as brave with their dollars now as they expected others to be with their lives.

The concern that takes its war profits and clings tenaciously to them, fearing to launch out for fear of losing some of them, and all the time knows that it is playing the fool part in reconstruction is going to have a mighty hard job showing why the term "industrial slacker" should not be nailed on its front door.

Our idea of a calamity would be for a civic candidate to make a speech and be banned from using the phrase "in the best interest of the city."

The statement is made that certain drug stores in the flu epidemic shoved prices sky high. There's a heap of folks in this country reaching out after blood money.

HAS MADE A SUCCESS IN HIS LINE OF BUSINESS

Frederick E. Rejall Went Into the Selling Business and Has Made a Good Connection

FREDERICK E. REJALL, Canadian Manager, H. Boker & Co., Inc., Montreal, Que., Agents, Novo Steel Works, Sheffield, England, was born in Brooklyn, N. Y., 1880. After leaving High School he entered in the export and banking business with one of the oldest and largest houses in New York City. After a stay of fourteen years with this concern he was called by and made his entry into the steel business with the firm of H. Boker & Co., Inc., New York.

F. E. REJALL

He spent one year in the New York and Chicago territories, when under the personal schooling of J. R. Boker, then manager of the Steel Department and now president of the company, he received a thorough training, both as to salesmanship and the practical handling of their various lines.

His quick adaptability to the practical handling of tool steel, being his hobby since boyhood days, soon became apparent to his employers, to the extent of their sending him to the quaint himself with the manufacture and heat treatment Novo Steel Works in Sheffield, England, to further ac- of the output of this mill.

Here, under the direct supervision of B. W. Winder, chairman and managing director of the Novo Steel Works, an inventor of the first high speed steel, "Novo," assisted by Mr. J. K. Jonas, senior director, he gained much valuable information, both as to the adaptability and handling of the steels produced by this mill. After a short trip through Holland, Germany and France, he returned to New York.

His firm, realizing the great future of the development of the tool steel business in Canada, decided to enter into the Canadian market. In January, 1909, Mr. Rejall was chosen to represent his firm in Canada with the title of manager, and offices and warehouse were opened at 332 St. James St., Montreal, their present headquarters. Although his first six months in this field were exceedingly trying and at times almost discouraging, his untiring efforts, energy, and stick-at-it-ness, quickly brought the success that was bound to result, so the end of the first year showed a good balance on the profit side for his company.

His knowledge of his business, his congeniality, straightforwardness, and efforts to satisfy, have gained for him the esteem and highest confidence of the trade throughout Canada.

Prior to 1800 all paper was made of rags. Since that time wood-pulp has formed the basis for all the ordinary grades of paper, including that used for printing newspapers.

Canada's first large paper mill was built in 1865, and produced 1½ tons of paper in 24 hours. To-day a modern paper mill produces from 250 to 300 tons in the same length of time.

Speaking of Napoleon

IT'S over a hundred years ago since they fought at Waterloo, and took Napoleon by the snout and told 'im what to do.

You see he had been all puffed up, his head was out of joint—in fact it got so big at last 'twas near the busting point. The folks in them days wouldn't stand no sass from Bonaparte, so they kicked the jumpin' daylights out of his old apple cart.

They chased him round the clover crop and underneath the barn, and planted him out in the sea where he couldn't do no harm.

It's just a way the world has got with nations or with people, it's a mighty dangerous thing to do, this shoutin' from a steeple. As long as folks will stay at home and mind their own affairs, and keep from vexin' others with their high-falutin airs, they'll find this world a happy place chuck full of milk and honey, and peace that Midas couldn't get with all his mint of money.

And they can travel far and near, or stay right on the stubble, and go or vamoose to their taste without a speck of trouble.

But it's quite another thing, by gum, and there's miles of stuff to back it, that there's danger stickin' everywhere when you're searchin' for a racket. You can't go stampin' on pet corns, or jumpin' off the track, for when the deal comes round again they'll cut you from the pack.

It aint no use to buck this rule or put on injured airs —the safest thing for you to do is mind yer own affairs.

—ARK.

Why Is The Kaiser At Large?

AN outraged world should guard carefully against any pussy-footing that seeks to create a "go easy" attitude in dealing with the German nation, especially that part of it responsible for the war.

Now that the war is apparently over there is a decidedly pronounced sentiment toward tossing buckets of mercy on a people utterly undeserving of any consideration.

The German people are not repentant. Had they the power they would unloose their submarines again tomorrow.

The Huns who brought Hell to this earth, who drowned babes and butchered old men, have got to come before the jury of the Allied nations.

A Kaiser at large means trouble. It means plotting and intrigue. It means that one of the grossest miscarriages of justice the world has ever witnessed has been perpetrated. It means that the assassin has sidestepped the noose.

The Allied court should have some very direct sessions with William Hohenzollern. As things stand at present the murderer is still at large.

"Get out and sell" is taking the place now of "Go out and tell them that we can't promise delivery for a month yet."

Eggs used to sell at 3 dozen for a quarter. But then a quarter used to look as big as three dozen eggs in them days.

Some of the letters that are coming to Canadian homes now are "made in Germany." However, there's no kick about it, seeing that the victorious Canadians are there making them.

The surrender of the German fleet may have been a great event, but it dropped the estimation of the Germans down to zero in the popular mind. After all no person loves a quitter.

MARKET DEVELOPMENTS

Some Prices Show Inclination to Modify

All But One Contract For Munitions Has Been Cancelled and Settlements For Cancellations Are Now Discussed—Pittsburgh Looks For Short Dip in Steel Prices Before Recovery

CANCELLATION has been written upon nearly every munition contract in Canada. The 12-inch American shell went by the boards this week before the actual business of production had been commenced. Large machine tools were in turn cancelled by the firm holding the contract from the American Government. In several of these cancellations—in fact in most of them—it will be necessary to do some considerable readjusting. Only one shell contract stands in Canada now, and that is the 240-mm. shell, an American model, the contract being placed in Brantford. If Washington decides to let this contract stand this shop will be employed for some months to come as the order was for a large number of these tapered projectiles.

Prices of steel show an inclination to come down a little more in a few lines. The element of competition is coming more and more into every business deal that offers. Firms that have been looking askance at the smaller orders are now out after them, big or little. It all means a tendency to put the pruning hook into the price list, and this has been done, sheets and bars showing a few more cents off this week.

There is something peculiar in the way certain lines of industry have recovered their producing powers. For instance, the Canadian trade had been told that it was impossible to secure skelp to make tubes, and that there would be no help for it until after the war was over. Canadian warehouses find that immediately on the cessation of hostilities great quantities of tubes are being rushed along to them at war-time prices. The belief is that the mills were holding a strategic reserve all the time. The placing of these tubes in Canadian warehouses at high prices means that there will be a scampering now to dispose of them before a further decline in prices, and selling profits will be forgotten, the idea being to get from under with the high priced material.

Scrap metal business is poor. It was poor last week and it looks as though it would be poor for some time to come. Dealers are not offering on any available material, and users are not in the market for any considerable tonnage. The feeling seems to grow that there will have to be a readjustment of the iron and steel situation before there is much of an improvement in the scrap metal trade.

CANCELLED BUSINESS WILL NEED TO BE READJUSTED NOW

Special to CANADIAN MACHINERY

MONTREAL, Quebec, Dec. 11, 1918.—The approaching holiday season, coupled with the recognized unsettled condition of general trade, has been a factor in continuing the nervousness shown during the past few weeks. Plants in this district that have been working on shell contracts, are gradually bringing their operations to a close, and within the next two weeks all work will be finished. Future work in these plants is more or less obscured at present, and few will give a decided answer as to their early activities. Steel mills in this district are still quite busy, but booked orders are lighter. It is very apparent that little activity will develop in any line before the turn of the year. The machine tool business is exceptionally quiet, notably in the placement for new equipment. Virtually, nothing is doing in old materials.

Little Buying for Futures

Uncertainty and hesitation are two of the chief characteristics in the present unsettled situation. The general demand for material is very quiet, but less difficulty is experienced in obtaining shipments of supplies. The market is virtually free of control features but with the high prices still effective possible buyers are reluctant to enter the field. Apart from the few cancellations that are reported, the mills are quite active, and the shock that might have been expected by theh sudden stopping of hostilities has, as yet, not been seriously felt in this direction. Of course the volume of business that is now being placed is considerably less than that of a few months back, but sufficient business is now on the books to maintain operations for many weeks hence. It is probable that the market will be free from all restrictions at the beginning of the year but it is unlikely that any sudden break will result in prices. The ship and car programme is still heavy, and the present demand for plates offers little relief for domestic purposes. This, however, will gradually right itself, and before the winter is over more normal conditions will prevail. It is believed that heavy buying will eventually figure in the steel situation, but consumers are apparently not anxious to cover future requirements at present high prices. What business is passing is for immediate needs only. Prices are firm and unchanged at last week's quotations.

Lead Prices Decline

Little of interest is passing in the metal markets, but the volume of business is sufficient to maintain the optimism generally shown throughout the trade. Copper is firm on quieter demand with castings one cent easier than last week, the present price being 28½ cents per pound. Tin is steady on a fair demand. The lower market in London has not seriously affected the local situation but the prospects are for lower quotations early in the new year. The lower price in the States has reacted on lead here and a decline of one cent is noted, the current quotation being 9½ cents per pound. Antimony and aluminum are both unchanged at 12 cents and 46 cents respectively.

Machine tool dealers are having a

holiday at the present time owing to the almost negative demand for equipment. The cessation of munitions making has eliminated the need for shell machinery, and activity for ordinary requirements is not expected until the readjustment period is well advanced. One of the problems confronting the trade at present is the settlement in connection with the cancellation of such tools as are in process of manufacture. Where considerable work has already been done on special machines the difficulty is more pronounced. This, however, does not apply to standard equipment and it is reported that work of this class of tool is proceeding as usual. While second-hand equipment is a little more plentiful there is not the volume that might be expected from the closing down of so many munition plants. This is largely due to the fact that the bulk of existing shell machinery is of a special character and adaptable exclusively to the purpose for which it was built. Many plants are holding on to their standard equipment, not knowing what may develop in the near future. Supply demand is very light, but in general the prices are well maintained.

Scrap Movement Quiet

Despite the marked decline in many lines of scrap and old materials last week the situation has remained very quiet, and trading is confined to supplying small quantities of material for immediate requirements. Dealers here are not anxious to accept old material for stock at prevailing prices, and purchases are invariably made at figures lower than those quoted, these being more nominal than actual. No further change has been made in quotations here and the market is expected to be dull for some time.

THEY ARE GOING AFTER TRADE NOW

And Prices Show Inclination to Fall Off In Some Lines Of Steel

TORONTO.—A softening of prices in several lines of steel products, a little more competitive selling, inquiries for lines that had been out of existence for some months—these things feature the Toronto market situation this week. Although none of them are outstandingly marked, still they indicate the direction of trade.

The Machine Tool Trade

Machine tool dealers in Toronto claim that they have not much single purpose machinery in their warehouses, and that a number of plants that they have taken over on the expiration of contracts contained a large percentage of general purpose tools. Cancellations of 12-inch American contracts this week brought in its trail cancellations amounting to some thousands—a good many in fact. That just about ends the munitions business in Canada. In fact about the only contract still living is that for the 240 mm. Motor Trucks at Brantford have that, and if this shop goes along with the work it will be a bit of souvenir in the industry that before long will be only a memory of quantity production and high wages.

One dealer stated this morning that his firm was receiving inquiries for equipment from several centres, and that business was beginning to take on a peace-time appearance. Some of the inquiries promised to run into considerable money. Of course, it will take a long time for this business to grow into the volumes that have been handled by the machine tool dealers in the last few months.

The supply business is smaller in volume this week. A number of decisions will have to be made regarding what lines are to be followed by Canadian manufacturers before there is much of a revival in this business.

The Steel Situation

The mills are not accepting cancellations from the Canadian trade, neither are they considering any price adjustments. As a consequence there is a considerable tonnage coming forward to the warehouses at old prices. The result is that there is going to be an effort on the part of the warehouses, on the arrival of these goods, to dispose of them as quickly as possible. The same rules hold in steel as in any other form of merchandising, and it means in reality that pricecutting will be indulged in. As a matter of fact there have been a number of deals put through in the last few days which show a tendency on the part of the dealers to get rid of their stock at the best price obtainable. Of course, this must not be taken to mean that the skids are under any considerable number of lines, but rather that the old business of competitive selling is again being felt.

"Simply as a matter of form." That seems to indicate the feeling towards the securing of permits from the war trade for orders that are being put through now. There is little delay in getting orders through, and the feeling here is that the whole business of government regulation and allotment is right now living on borrowed life, and is apt to go by the boards almost any time.

A Peculiar Situation

Tubes are coming forward to Canadian dealers in large lots. In fact they can get all the tubes they want now, and almost any kind, or size. Some of those interested in the trade are rather skeptical about the remarkable recovery that is being made in the ability of the mills to furnish the supplies of tubes to Canadian dealers. The tube situation was bad for a good many months. In fact it was impossible to secure a two-inch tube and they were badly needed for repair work. Canadian dealers were told, when they approached the mills on the other side, that it was impossible to give them the stocks they required. Their mills were entirely on war work, and furthermore it was impossible to secure skelp to send to the rollers as the metal was passing through the open hearths to other purposes. Now, almost the day or week that the armistice is signed, the Canadian dealers are informed that their orders, accumulations of weeks or months, are on the road. Certain it is that the tube rollers could not have recovered so rapidly, and it looks as though they had been keeping a strategic reserve against a bad day, and that the Canadian dealers were now being avalanched from this. These tubes are coming in at a fairly high price, and, of course, there will be more or less of a scramble to place them before the era of high values has become a memory. They will likely be sold at a price very close to cost in many cases.

Some Price Changes

As each week, some months ago, saw prices another rung or so up the ladder, so each week now sees the prices crawling down again to levels approaching reason and stability. Sheets (28B) are this week quoted at $7.50 hundred. Last week they were at $8, and not long before that they were trading at $9, and even a little better in some cases. The chances seem to be that they will hang

POINTS IN WEEK'S MARKETING NOTES

The scrap metal trade continues in a state of stagnation in Canada. No sales of any size are being made. Yards are well stocked, in some cases with goods bought at prices that cannot be realized in selling.

Prices of steel sheets and steel bars are down slightly again from last week's quotations.

There is a good deal more competition now for any business that is offering to the warehousing firms.

The contracts of the 12-inch naval shells have been cancelled by the U.S. Government. This leaves only the 240 mm. contracts for the U.S. Government, and this order is in the shop of Motor Trucks, Ltd., Brantford.

Dealers in wood working machinery report more inquiries from a wide radius than has been the case for some months.

Trade expects that the whole system of government permits for steel will be done away with in the very near future. Permits are still obtained simply as a matter of fact.

Pittsburgh experts figure that steel prices are due for a dip shortly after fixed prices run out at the end of the year. After that a buying rally at the reduced values will start a real boom at the steel mills.

up around the $7 or $7.50 mark. Steel bars are quoted down a little, $5 against $5.50, and iron bars, $4.90 against $5.25. Small shapes, and this heading includes a large variety of material, is placed 25c per hundred down at $5.50 against the $5.75 that has held for some months.

Dealers state that the demand for steel goods is brisk. Business that has been neglected for a long time is coming to life. Apparently the demands come from industries affected principally by the trade of the mines, agriculture and ship building.

Scrap Trade the Same

It may be that the Canadian scrap metal trade is waiting for the U.S. market to make a start. The U.S. market in turn is waiting for the end of the present quarter to run out, as prices are fixed by the Government up to that time, and present demand does not warrant the paying of the limits unless there is a case of real need and quick disposal in connection with the deal.

At any rate conditions in the scrap trade in Canada are almost stagnant. Last week Montreal dealers came out and cut the prices they would offer by big margins. Lines that had been holding around $24 per hundred were brought down to around the $15 mark, but apparently that made little difference. Buyers are not found at either price. As one of the dealers in Toronto stated this morning, "What's the use of naming a price at which you will buy when you don't want to buy anything, and what's the use naming a figure at which you will sell when there's no one in sight who wants to buy?" Well that just about represents the case here at present, and there is nothing in sight at the moment to indicate that a period of greater activity is in sight. Yards are well stocked, too well in fact, and for the present nothing is moving.

SCRAP DEALERS WAITING FOR IRON AND STEEL MARKET TO SETTLE

THE scrap metal market last week was described as stagnant, and this week a phrase that would fit the situation would be more stagnant. This condition is the same on either side of the international line. Canadian dealers who used to find an outlet for much of their yard tonnage in the American markets are finding no such outlet now. Buyers at U. S. points are not any more anxious for material than they are here. Prices have much to do with the difficulty. These have been for some time at the maximum allowed by the Government. There is a strong tendency now to get away from these, and in this condition much trading is not looked for. Reports from American points give the following:

Chicago—Prices are unsettled here, as there is almost no trading on which to form an opinion. Many of the smaller dealers are out now offering much of their material to the consumers at concessions, but they are not meeting with response even on these grounds.

Pittsburgh—Present Government prices are effective only until the end of the year, and no person is buying in the meantime. Cancellations are made wherever there is any chance, and users are becoming more strict than ever in their inspections, and if the metal is not right up to scratch the rejection of the shipment is certain to follow.

Buffalo—The trade here seems to incline to the belief that all Government control will disappear at the close of the year, and it seems to be the opinion of nearly all that an all-round reduction of $5 per ton will be certain. Both mills and scrap men are waiting for developments.

Cleveland—Dealers are positive in their statements that they will not contract for any material before the first of the year. When the free market comes a break in the prices is looked for. Cancellations show a strong inclination to become more numerous, and although the tonnage affected yet is not very large, a continuation of the tendency might become rather embarrassing.

St. Louis—Sharp cuts were made in the price of many lines here this week. But even the whittled prices hardly represent the real value of material at present. Neither has the cut had the effect of stimulating trade. A few weeks ago dealers claimed that they were shy of all grades of scrap, but as soon as the war ceased they all turned out to have very large offerings to place on the market. They had loaded up at fairly high prices and now they are scampering to unload before the sag in the market becomes any more pronounced.

Birmingham—Dealers here have their own way of figuring out the situation. They hold that not until there has been a settlement of the steel and iron situation will there be any betterment in the scrap business. In any trading that does take place consumers simply make their own bids regardless of price lists.

STEEL PRICES WILL TAKE DIP BEFORE BRISK BUYING STARTS

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Dec. 12. — The opinion expressed in last report that there will be no further price fixing is now confirmed and only the final formal announcement is needed to wind up the obituary of Government price control. The War Industries Board and the iron and steel industry independently reached the same conclusion, that price fixing should be discontinued. There appeared to be some weight to the idea of some measure of control of prices during the transitionary period, so as to avoid a slump in prices, but the War Industries Board found itself powerless to enforce minimum prices, to prevent sellers from shading, while the producers felt that in the long run they would be better off if the market were allowed from the very outset to take its own course. One cogent reason for the producers' attitude was that if the War Industries Board should set prices for the first quarter of the new year it would probably insist upon reductions as it would not be readjusting the market if it did not make at least a start, whereas the producers might be able to hold the old prices for a time.

Immediate Decline Improbable

While the situation created by the sudden disappearance of Government control—although, of course, the present agreement runs through December 31, which is not far off—appears to be an entirely new one it is not new after all. It is in substance the same situation that has always developed after there has been a rise in the market and the corresponding decline is in prospect. The market moves through cycles, which are very much the same in character, although differing in length and in the intensity of the movement. Starting with a period of low prices, demand develops, prices begin to ascend and buyers become confident. They buy more and more freely and thus encourage prices to rise further. When prices stop advancing the buyers find themselves well covered and cease buying. Then the producers hold prices as long as possible, shipping on old orders and booking such little additional business for early delivery as develops. No large sales can be effected on a declining market, hence the incentive to the producer is to hold prices, for there is more profit for him in the contracts he has on books than there would be in the little business he could pick up by cutting prices. When order books are pretty well cleaned out the sellers begin cutting prices and the decline occurs. Beginning with the boom of 1899 this cycle has been run through five times, the peaks of demand and prices falling in 1899, 1902, 1907, 1909 and 1912. Afterwards in each case, there was a period of sustained prices with little buying, but heavy shipments. After 1899 and 1902 the old pools and associations helped to sustain the market, and in 1908 the "Gary dinner" movement was a great help, but the underlying incentive to the individual producer, not to cut prices, was always present. The artificial assistance given, as by the Gary dinners, merely helped.

In its general form, the situation today is precisely similar to those experienced in the past. The furnaces and mills have a large volume of contract business on books, and there is a fair, though decidedly moderate, running demand in the aggregate for early deliveries, from buyers to whom price is no particular object because they expect to turn the material over at once. If the market is going to decline eventually, they do not wait, because then they can buy more material and turn it over also. In this class are the jobbers and automobile builders, for instance.

As to the contract business on books, some of the contracts are absolutely firm contracts when, for instance, they are for specific buildings or bridges, or specific lots of railroad cars. About this business there is practically no question; it must be carried out. Other contract business is not so firm, and the buyers under the contracts may be altogether unwilling to promise that they will take out the entire contract tonnage, which might involve a period of many months, but they are in many cases calling for immediate deliveries. They may be urgently desiring such and such tonnage deliveries for January, and perhaps also for February, and that affords business for producers even though there is no assurance as to whether these same buyers will want material in March at the contract price.

Little Construction Work

There is little construction work in prospect for the near future. There is practically nothing by way of entirely new projects, and as to old projects, set aside by the war, the buyers in many cases are at the mercy of the labor market and the market for other commodities, needed in conjunction with the steel. There is specific information as to several such projects, where large tonnages of steel have been under contract for months, and the buyers now tell the mills they will want the steel as soon as they can secure labor to utilize it. Just when that will be they do not know, but they are anxious to go ahead.

As to new projects, little can be expected for a time. Regular investment buyers, who would build factories, bridges, hotel and office buildings, cannot take hold now for they require assurance as to costs. They cannot make their investments at high costs if costs are shortly to be lower. It is not merely a question of the cost of steel, for the cost of utilizing the steel, by buying other construction materials and employing labor, is a large item in most cases, and if steel came down to an entirely satisfactory level at once these investors would still have to wait for their other costs to come down, or for assurance that costs were not going to come down. Accordingly, the iron and steel producers do not see that it would help matters in any way, while it would hurt the situation in several respects, for there to be an immediate and material decline in prices.

Market Prospects

It is barely possible, of course, that there will be declines immediately after January 1, but it is much more probable that existing prices will be held for a time, perhaps a few weeks, perhaps several months. Meanwhile the buyers who can afford to take the risk of buying at present prices, because they can turn over the material promptly, will be over their rush and much of the contract business will be worked off. Production will doubtless decline, perhaps very materially. Finally, when prospects appear ripe that heavy buying for forward delivery can be induced, producers will be ready to meet buyers' ideas, by dropping the market, and there is likely to be a dip to such an extent that it will be followed promptly by a recovery, and then the period of prosperity, probably of several years' duration, will be upon the trade.

CANCELLATIONS ARE NOT BEING ACCEPTED BY PIG IRON MAKERS

THE question of cancellation of contracts is occupying considerable attention among the producers of pig iron in the United States. The situation is a rather peculiar one. Many orders were placed on the books of the companies, the price to be the Government standard at the time of delivery. Now that the furnaces can supply this material, in many cases the demand for it has been withdrawn, or in other cases the users want to hold back and see if the market will work toward a lower level before they place their orders. Cancellations are not being accepted, and in some places iron is piling up on shops faster than they can hope to use it. Their only recourse will be to come on the Government for loss. Following are some of the reports from leading production centres in the States:

Chicago—In no case reported here has there been a cancellation on gray iron. Cancellations for any kind of iron are not being accepted. Some requests for cancellation ask for a bill of expense for work done on the order up to the time of cancellation, in order that the matter may be taken up with the Government. Sellers refuse to do this, advising that melters sell their iron on the market and charge back the loss to the Government. The idea is that the market will be disturbed less in this way.

New York—There have been quite a number of requests made in this district for cancellation, but the furnaces are standing pat and refuse to move in this direction. Furnaces remind the trade that in the summer of 1917, when pig was selling at $50 and $55 per ton, they kept on filling old contracts at as much at $20 below that mark, and now that the tables have been reversed, they hold that it is up to the melters to keep faith with the sellers. Makers of pig are emphatic in their stand that contractors for iron must take their deliveries.

Buffalo—Small tonnages for early shipment form a good deal of the new business that is coming to the furnaces here. Furnaces which are not soliciting business are those which are going ahead on the allocations made by the Government prior to the cessation of the war. Coke shipments have been more satisfactory than for some time past.

St. Louis—Makers of pig iron in this district are satisfied with the prospects for business in the future. Those who expected that there would be a cancellation on a large scale are out in their guess, for many of the firms that were getting iron on allocation are just as keen to get it now as though the war were going to last for a year. Peace plants are coming to life much sooner than was thought possible. Construction work is about the only line that has not begun to take on definite form.

Cincinnati—Although it was hoped that the end had been seen of cancellation requests they continue to come in. Against this there is reported new business from firms making agricultural implements, although the volume of this trade is not as great as that which is being dropped. Foundries casting for machine tools are in a poor way, as they have no outlet for the pig iron that is piling up on them. At present they are storing for future use.

Philadelphia—Cancellation by the British Government of an allocation of 100,000 tons of basic is causing some worry among the dealers here, and a meeting may be held to consider the whole matter. There is another matter of trouble. Sellers booked orders months ago that they plan to fill now, and they are wondering if they can hold users up to prices should the Government regulations be done away with before delivery is made.

Pittsburgh—Many furnace men hold the belief that the dropping of Government control will mean higher prices. They point to the fact that production costs are steadily rising, and that there are stacks that at present prices are not doing better than breaking even.

NEW ADDITION TO THE GALT FOUNDRY

Galt.—As another evidence of the continuous growth of Galt's industries, particularly on the east side of the city, the Galt Foundry Company, situated on Beverly street near the C.P.R. subway, who specialize in the manufacture of sprinkler stokers, have found it necessary, owing to the large extension of their business, to erect a new machine shop, operations having already commenced on the building, the dimensions of which are 65 by 60 feet and 20 feet in height. The manager, Mr. W. M. McRobert, stated that the company would eventually build a new factory, as there was every prospect of the business growing to large dimensions in the near future. With the present addition to the plant, it will be necessary to take on a number of extra employees.

Other industrial establishments in this locality who have built additions to their plants within the past twelve months, are the Galt Brass Company, macadamized road; the Roelofson Machine Tool Company, and the Galt Machine Screw Company, the two latter also situated on Beverly street.

THE WEEK IN INDUSTRIAL HAMILTON

Special to CANADIAN MACHINERY

Hamilton, Dec. 12.—The Smart-Turner Machine Company, who have been manufacturing steel barrels for the last four years, state that the barrel industry is rather a strange one to handle, inasmuch as it varied from the regular business, by the fact of the orders coming into the plants in the early months of the spring and summer, and that business was almost at a standstill during the winter months.

The backbone of the barrel business is in the welders, who are large salaried men, and who demand a year's work. In order to keep the welders, so as to have them in the time of need, it is necessary to find some occupation for them, where they can earn their wages during the almost idle period of the industry. Last winter the welders in the Smart-Turner plant were engaged for a portion of the time in laying new floors in the factory, and machine shop, and repairing machinery, and odd jobs in welding, and the few odd orders for barrels that might be received.

In 1915 the Smart-Turner Company received an order from the Imperial Munition Board for 24,000 barrels, which were to be made of 14 gauge sheet iron, and to be filled with oleum for shipment overseas. During the year this order was filled, under the direction of Jack Howard, then superintendent of the factory. The order enabled the firm to instal an up-to-date barrel shop, but in 1916 they had the shop and no barrel business. In 1917-18 they began to work up a business, and during those years received their share of the barrels which were purchased in Canada.

The number of barrels that are consumed annually is very small, stated Mr. Smart. In the Dominion of Canada the consumption is almost limited to three companies, the British American Oil Co., the Canadian Oil Co., and the Imperial Oil Co. One of these firms in 1918 made very small purchase, while the others were limited in the numbers that they stocked. This may be due to the fact that several oil companies are themselves interested in barrel manufacturing.

The Standard Oil Company in the United States manufacture more barrels than their own consumption, and supply barrels to the firms with whom they are associated, thus the Canadian manufacturer cannot compete with the Standard people. The wooden barrel has by no means become a thing of the past, is the statement made, as a matter of fact they are still being used extensively by the oil companies and others.

The barrel trade has had queer turns in it, according to those who have been closely associated with the industry. It is stated that requests have been made from firms in South Africa and Italy, that barrels be made by the Smart-Turner firm, and be forwarded to a refining company to be filled with oil, gasoline, acid, or some other commodity. In event of the firm taking this in hand it would change them from the barrel manufacturing business into that of a broker or oil company. Under pre-war conditions it was possible to carry out these instructions, but due to the increased freight rates, the advanced price of the contents required for the barrels, the matter of export became almost impossible.

Export Not Feasible

The question of exporting barrels is one that has been deeply considered, and investigated. The firm have found that due to the difficulty in shipping that it is not a feasible idea. Shipping space is sold by cubic space and weight, whichever is the larger. In order to hold down the shipping charges, and to supply weight in order that the vessel will become seaworthy, the barrels have to be filled, thus the contents of the barrel becomes many times more valuable than the barrel itself. Great difficulty was experienced by the Imperial Munition Board in shipping barrels overseas. They required that the barrels be filled with oleum, a very strong sulphuric acid which, when mixed with water, eats into metal at a very rapid rate.

At the port of St. John, some time ago, a large number of barrels made by an American firm, from a light gauge of metal, filled with oleum, were loaded into a ship for export to England. In some manner, it is not known how, a quantity of oleum and water were mixed, with the result of it eating through the metal and the contents of several barrels spreading over the others, placed close to each other, resulted in large holes being eaten in the barrels, and the oleum again came in contact with water in the bottom of the ship, and its action eat holes in the bottom of the boat to such an extent that the ship began to sink at its moorings in the harbor, and was only saved from submerging by being brought back to a dock and being tied there.

This resulted in the Imperial Munition Board instructing that their barrels be made of a heavier gauge. However, they have not shipped any further consignments of oleum, but filled the barrels with other fluids required overseas.

It is upon these grounds and many others that have been brought to the attention of Mr. Smart that he has arrived at the decision that the steel barrel as an export product is not a profitable one, and on the facts that the number of barrels used in Canada is limited, that he makes the statement that there is not enough barrel business in Canada to keep all the barrel shops in constant operation.

The Labor Situation

The labor situation has been greatly relieved in this city, during the past several weeks. An example is demonstrated in the fact that a local concern advertised for a man to fill a vacancy on their staff and received 106 applications for the position. The same firm advertised for the same class of man about a month ago, and received only one applicant.

The large numbers of troops who are being demobilized is said by local concerns to be the cause of the labor flood. Many men are now looking the daily want ads. over for a position. Some applicants are not out of employment, but are on munition work and are seeking to secure permanent positions before the respective firms they are working for close down on munition work. The shortage of expert mechanics is still in effect, however.

Orders Cancelled

The Canadian Cartridge Company at Hamilton, who announced that they were to enter into the field, manufacturing all small steel vessels, exclusive of the boiler trade, and who had an order from the Imperial Government for 3,000 barrels, have announced that the order has been cancelled, and that at the present time they have no orders on their books for any kind of metal receptacles. Mr. Cook, superintendent of the factory, stated that he did not know when the company would commence operations along the line of their new proposed product. Over $100,000 has been invested in machinery to proceed with the manufacturing of steel barrels.

MAKING PUMPS

A very large number of pumps are being made by the Smart-Turner Company for the Embarkation Service of the United States Government. The sizes that are being erected are 10 x 6 x 12 Vertical Simplex, brass fitted, and 4½ x 4 x 6 Vertical Simplex. These are to be used on mine planters and river steamers in the service of the United States Government. The order is large enough to keep the Smart-Turner factory engaged in their exclusive manufacture until the end of February, 1919.

"Bang!" went the rifles at the manoeuvres. The pretty girl screamed a surprised little scream and stepped backwards into the arms of a young man.

"Oh!" she said, blushing. "I was frightened by the rifles. I beg your pardon."

"Not at all," said the young man. "Let's go over and watch the artillery."

Re-Educated Soldiers in the Machine Trade

Vocational Re-education, Together With Artificial Limbs, Make the Injured Soldier Entirely Self-supporting and Enables Him in Many Cases to Earn More Than in Pre-war Days

By KATHARINE FREEMAN

THE old idea of supporting the cripple through charity has been uprooted and the public made to understand the idea of re-construction and re-education. When we hear of a man whose earning capacity has been increased since his injury, we feel that the work of reconstruction is an assured success. One such story is of a mechanic, who was wounded while serving in the Princess Pat regiment. He was sent back to Canada, spent three months in a convalescent hospital, and is now earning twice as much as he earned before. He is now foreman of a machine shop.

According to the Vocational Rehabilitation Act recently enacted by Congress, those disabled in the military and naval forces of the United States have been placed under the joint authority of the Surgeon General of the Army and the Federal Board for Vocational Education. The Surgeon General has jurisdiction from the time the person is injured until he is restored to good physical condition, when he receives his honorable discharge from the service. The Federal Board then offers him vocational re-education and training, which will enable him to return to useful active employment, and the U. S. Employment Service will find him a job.

The method is first to supply the cripple with a mechanical device in place of the missing arm and leg, then to thoroughly train him to use these substitutes in the performance of his work. The number of positions open to the cripple is far greater than a person who has not given thought to the problem would expect. Any man, who is able to get about on artificial legs, can do all but the heaviest work in machine shops. A man with one arm can do lathe work, drill press work, milling machine work and planing. Many of the processes performed in a machine shop are heavy, but there are also many which are light. It has been found that there are fifteen which can be performed by a disabled man.

TEACHING THE RETURNED SOLDIER THE USE OF OXY-ACETYLENE APPARATUS

Men having minor injuries of the body, but capable of standing, and having both hands, can still perform the following processes: drilling, grinding, milling, light planing, shaping, boring, screwing, sawing, operating of power press and capstan lathes. In the skilled trades, coppersmithing offers an opportunity to a man crippled in certain respects. Free movement of the body, however, is necessary as well as the use of both arms. Cripples are qualified to perform the operations of fitting, turning, brass finishing and moulding. For patternmaking a man must have good eyesight, although the loss of one eye would not make the work at all impossible for him. Oxy-acetylene cutting and welding is a vocation which furnishse one of the best opportunities for the re-education of disabled soldiers. They can be trained in oxy-acetylene cutting and welding so that at the end of three months they are self - suporting. Moreover, the demand for welders greatly exceeds the supply. In addition to all this, the industry has ahead of it such a future as few can look forward to.

The super-minds of the country may be developed among the war cripples, if experiments now in progress bear results. Students of the amazing psychological changes brought about by the loss of an arm or a leg are looking for surprising things from these researches. The surface of the possibilities has only been scratched, as yet, but the observations so far are more than encouraging.

The idea that a wonderful brain de-

RECEIVING TRAINING IN THE USE OF OXY-ACETYLENE WELDING APPARATUS.

velopment may be possible for cripples is based upon the known fact that the loss of one sense quickens another. A blind man usually develops a startling sense of touch. The amputation of an arm or a leg also produces, in many cases, an increased brain activity. A recent case in point is that of a cripple whose inventiveness brought him a comfortable fortune.

It appears that many nervous persons who have undergone an amputation operation become patient, careful and painstaking, which results in an improved output of work. Men who were once rovers declare that they no longer feel the roaming spirit. These and many other altered characteristics point to the fact that a radical mental change takes place in the individual after he has lost a portion of his physical self.

While public interest is easily focussed on the war cripple, it is not so easily directed sympathetically to the case of the workmen who are injured in the shops. These cases have been so common that they have attracted little attention. Yet they greatly outnumber the cases of soldiers permanently hurt in battle.

The advisability of including them in the government program of caring for the injured among the military forces, has been brought to the attention of Congress. It is quite possible that something will be done along these lines. These industrial cripples are quite as able to work, if properly re-educated, as the soldier. The matter is one which is already receiving considerable attention among progressive business men.

The urgent need for developing the iron and steel industry of the province was emphasized by C. F. Law, chairman of the mining bureau of the Vancouver Board of Trade, in speaking to the provincial convention of the British Columbia Boards of Trade at Vancouver.

ELECTRIC STEEL FURNACES

Before the war was many months old, armament makers found themselves accumulating huge quantities of borings, turnings, screwings, etc. of high-grade steel, produced chiefly in the process of boring and planing shells and guns. In ordinary times these turnings, etc., were of comparatively little value, although they contained chrome, nickel, and other costly elements. The real difficulty was to remelt them without losing these valuable contents. When the munitions works began to make enormous quantities of these turnings it was realized that the best way of utilizing them and of economizing steel was afforded by the electric process of melting, or remelting or refining. Admittedly there was no really perfect electric furnace of large dimensions on the market; but it was recognized that by the electric process it was possible to remelt without losing a large percentage of the alloying metals. All the nickel and almost all the chrome could be saved, and the turnings thus converted into first-rate steel. Sheffield, which had stuck tenaciously to its crucible, was specially interested in this scrap problem, and several local engineers and metallurgists turned their attention to the improvement of the electric process. The result that two types of purely Sheffield-invented electric furnaces have been put on the market and are being widely adopted, while other types are being employed on a great scale and are being constantly improved.

In briefly describing these Sheffield furnaces—the Greaves-Etchells and the Stobie types—there is no intention to ignore the virtues of others. However, it may be said that until their introduction there was no type of electric furnace of any considerable size that could melt more than a limited percentage of turnings per heat. Large quantities of new raw materials, such as pig iron, bar iron, etc., had to be used along with the turnings and similar scrap. Now, it is possible to have "boils" of as much as 12 or 15 tons entirely of scrap, such as turnings, against a limit of about 2½ tons before the war. This great development in electric melting will no doubt stand out as one of the most important metallurgical events of the war, and as a mark in steel trade history second only to the discovery of the Bessemer process. These large electric furnaces can turn out steel which makes sound ingots, and at less cost than the crucible process, though it may be a long time before the crucible is discarded for the making of tool and other special steels. The electric furnace, indeed, may simply prove a valuable addition to the crucible and the converter, just as the electric light has to gas, without displacing it.

The joint inventors of the Greaves-Etchell electric furnace are both Sheffield men, the former an electrical engineer and the latter a metallurgist. The furnaces are made in sizes of ½, 1½, 3, 6, 9, and 12 tons capacity. The smaller sizes can run a charge every 2½ hours, or nine charges a day, giving an output equal to 36 crucibles of 56 lb., and they can be operated by one skilled man, one unskilled man, and a boy for the ammeter, against 15 men for the crucibles. Again, the cost of renewals is much less with the electric than with the crucibles, and the space occupied is also smaller. This type of furnace is finding favor in America as well as at home.

Mr. Stobie, another Sheffield man, has aimed at eliminating the chief defects in the larger types of furnace. Previously electric furnaces of any considerable size were apt to suffer from localization of heat to the region of the arcs, rapid destruction of the roof, cutting away of the electrode holes, rapid tapering of the electrodes, and quick loss of heat after tapping. These defects were mainly due to the difficulty of stopping up the gaps around the electrodes where these passed through the roof. The Stobie furnace can be completely sealed up, and as there is no chimney effect no cold air is drawn. A reducing or carbon depositing atmosphere is constantly present. All surface combustion is arrested. The whole of the original sectional area of the electrodes is available for carrying current. The electrodes are of small diameter. There is no heat loss and no waste of current from escaping flame. The electrode holders and gear keep cool without water-coolers. The workers are not subjected to excessive heat. After tapping, the heat is retained as in the open-hearth furnace.—"Engineering Supplement, London Times."

Shovels Made Out of Old Locomotive Tires

Scarcity of Plate—Demand For Shovels and Availability of Scrap Materials Result in New Use For Locomotive Tires With Higher Quality of Finished Product

By W. S. STANDIFORD

THE great world war has created an unusually heavy demand for shovels as they are used in the trenches abroad as well as in the training camps. As a result, mills and factories are rushed with orders for these useful implements which they are endeavoring to fill. Shovels are made out of steel plate, produced by the aid of rolls, which wear out rapidly and require replacement. In these days of railroad embargoes and roll foundries being so swamped with orders, it is impossible to get new rolls made in less than three months. The problems faced by the manufacturer of shovels to keep his output up to its maximum is a very serious one. The demand for steel bars to make the plates out of, is also very heavy, and being out of proportion to the amounts rolled, also causes delays in shovel shipments.

The use of waste materials and their conversion into various useful articles having different shapes, is receiving the attention of various mill and factory managers as it is realized that a considerable saving of money can be effected by purchasing old worn metal, and re-rolling it to the desired sections. Worn steel locomotive tires that have outlived their usefulness in that particular field, when rolled into shovel plate, make most excellent shovels, as the quality of the steel is of a very high grade and better suited to the rough usage that the average shovel receives, than one made out of new steel containing a lower carbon content. The use of old locomotive tires is admirably suited to shovel manufacture, and will enable quick deliveries to be made by the mills, which otherwise would have to wait until their raw materials could be received. Having stated the advantages to be derived by the use of this metal, I will now take up the constructional details of the rolls used to reduce the tire into plate.

As the tires are of a circular section, they will have to be cut into halves before they can be used in the rolls, which can be done by sawing them either hot or cold. The method used by one rolling mill is as follows: A heavy cast-iron plate having two projecting lugs on its surface opposite each other is secured to a suitable foundation, and placed in a horizontal position with the lugs facing upwards. Fastened to the plate at a suitable distance is a hydraulic jack, so arranged that its plunger will exert pressure against the tire. The operating lever being conected to a small steam engine, the tire is placed in the frame and nicked at the sides with a cold chisel, the engine then being started. In a very short time, the tire separates into two halves, breaking at the nicked parts.

A number of them are then put into the heating furnace and heated evenly through; it being most important that there should be no cold spots on the steel, as it interferes with the proper working of the metal in the rolls. The roughing rolls depicted in Fig. 1 are three-high. This enables them to reduce the metal very quickly while it is at a white-heat.

There are different methods used to reduce the flange on the tire adopted by various mills, the designs of the rolls usually being such as is suitable to the engine power and other requirements of the plant. In the set shown in Fig. 1, the flange is rolled back into the main body of the tire; the sides of the pass having such a steep angle as to allow the bar to spread sideways in it. The heated metal is pushed by the rougher into the deepest groove in the rolls; it is then turned over before insertion into No. 2 pass. This allows any impurities in the steel, which generally comes out on the surface, in the form of scale, to drop off. The scale is loosened from the bar by small streams of water flowing on the steel while it is in the rolls. The action of the latter on the metal in the first pass also straightens the steel out in bar form, which makes the handling of it in the other passes easier. As the metal goes through each groove, it is made thinner, wider and also lengthened—these depending upon the amount of carbon and also the quality of the steel.

Locomotive tires used to be made out of crucible steel, but they are rolled out of open-hearth steel nowadays, as it has been found out by experience that the open-hearth process makes good reliable tires. After rolling, the bars being about 8-inches wide by ⅝ of an inch thick, are cut into suitable lengths, being about two feet long, and put into a heating furnace and re-heated. They are then ready for the sheet roughing rolls illustrated in Fig. 2. Each one is 36 inches long and 26 inches in diameter and made out of chilled cast iron. These rolls are turned with level surfaces. The two-foot long bar is given two passes, it being inserted crosswise, the rolls being lowered by means of the screws on top of the housings before the hot bar is run through the rolls. The cross rolling that the metal receives, makes it wider; the length being nearly the same. It is then turned at a right angle to its previous position and given one pass lengthwise through the rolls, the latter being lowered before the metal is run through them.

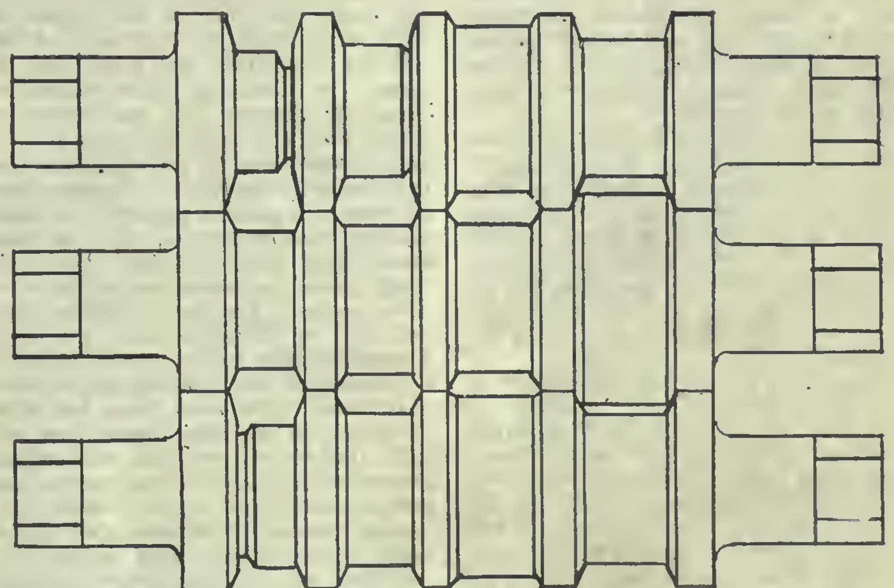

FIG. 1—Roughing rolls used for breaking down the old locomotive tires into bars, so that they can be used in the sheet roughing rolls. The violent change in section removes the crystallization of the worn tire and makes it into a fibrous nature—which is the condition that makes for strength in iron and steel.

The bar is now about ⅛ of an inch thick and is ready for the finishing rolls depicted in Fig. 3. These rolls are 22 inches in diameter by 26 inches long. As will be noted in the illustrations, one roll is turned straight, while the other has a concave surface. The amount of roll curvature shown on the drawing is purposely exaggerated, in order to make the picture clearer, the actual amount of surface curvature at its deepest part in the centre being about six one-thousandths of one inch.

It has been found out by experience that the thinner the plate rolled, the more concave the roll surface should be. This is in turn modified by such factors as the proportions of the diameters of the rolls to their body length; the gauge of plates rolled and also whether they are operated with or without streams of

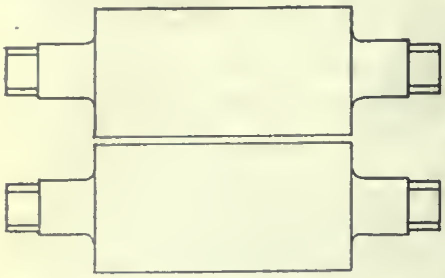

FIG. 2—Illustrates the sheet roughing rolls. the use of these rolls enables the finishing rolls to remain longer in the housings before requiring dressing. thus saving money and reducing the costs of manufacture.

water flowing upon them. The speed of rotation also has its influence on their smooth working. The reason why they require to be turned with a concave surface, is, that they expand by the heat, the centre of the rolls being actually larger in diameter than the parts at either ends of the roll body. By having sufficient curvature, they expand so that their surfaces are straight and level. If a set of sheet rolls were turned level and used to make thin sheets, the latter would buckle badly and become useless. It will be noticed in Fig. 3, that only one roll has a concave surface—the other being turned straight.

In practice, both rolls could be turned with curved surfaces; in this case, it would be necessary to divide the total depth at the deepest part of the rolls (which is the middle of them) between the two rolls. They would then possess straighter peripheries, the curves not be-so deep. By the use of rolls turned either way plates free from buckling are obtained.

From an economical standpoint it is found quicker and cheaper to turn one roll straight, and the other concave, as it would take nearly double the time to turn both rolls with a curved surface than it would require to finish one, it taking very careful and accurate turning on the roll turner's part to make them operate smoothly in the mill. Having described the reasons for curving the surfaces of the finishing rolls we will now take up the rolling of the steel to the desired gauge. The metal is transferred from the No. 2 set of rolls to the No. 3 ones. It is given three passes lengthwise, the screws being worked after each reduction until a thickness of 1-16 of an inch is reached. After each heat is over, water is turned on the No. 2 set of sheet rolls, the finishing set being worked with a continuous flow of water in small streams while they are in operation. In shovel plate manufacture, it is desirable to keep the rolls working in the housings as long as possible. As a general rule, the surface of the rolls wear hollow in the middle long before their centre surfaces get too rough to make good plates. This necessitates frequent dressing, which takes time and costs money. In order to make them last as long as possible, one company devised a rigging which attaches to the front of the housings, whereby, wooden blocks fed with emery powder are pressed against the bodies of the rolls, a short distance from each end, next to the journals. This prevented them from getting too deep in the centre. The rolls were ground every Saturday afternoon, after the day's work was done, the method proving very effective, the No. 2 set being in the housings five weeks before requiring dressing. The No. 3 or finishing set were also scoured with emery when they required it. The emery scouring method enables both sets of rolls to be kept longer in the housings than would be the case if it were not used. Rolls for making tin plates, which are very thin in gauge, are also turned concave. These rolls need more surface curvature as they expand considerably by the heat.

Tin plate rolls are usually from 24 to 26 inches in diameter, the length varying. A roll 24 inches in diameter by 32 inches length of body, should be turned 1-16 of an inch deeper in the middle (measured by a caliper) than at the ends next to the journal or necks. In other words, the depth of curvature at the lowest part of the roll, should be 1-32 of an inch on each side of the roll. If the latter are more than 26 inches in diameter, more concavity should be allowed. The temperature at which iron and steel is finished is of great importance to the appearance of the product. Too high a finishing temperature will cause a thin layer of scale, which a strain of bending will make them break away from the metal and leave rough spots, the appearance of the sheet being spoiled. Too low a finishing temperature, on the other hand, will yield a spotty-reddish surface which is prone to oxidize or rust. Sheets are finished in different styles, some being left black in color just as they come from the rolls. Others are covered with copper, aluminum, or tin—a mixture of tin and lead is also used to coat sheets for roofing purposes, which are called "terne-plates," they being used extensively. And last, but not least, large quantities of sheets are made coated with zinc which are sold under the name of galvanized sheets.

Steel sheets have replaced iron ones to a large extent. But the great increase in the use of steel is not without its drawbacks. Our galvanized iron and tin plates are no longer made of iron, but of steel, which metal is by no means as durable; nor does the coating of zinc or tin adhere so strongly as it did upon the softer and more porous iron plates which were used before the steel processes were developed. As a general rule, steel whether in the form of pipes, sheets or bars, etc., corrodes much quicker than iron when exposed to the weather. This is due, no doubt, to steel being much purer in quality than wrought iron, the impurities in the latter hindering corrosion. The method used by the roll turner to turn the proper curvature on the one roll will be interesting to the readers of this magazine, it showing the manner in which the work is done. The first thing done is to turn one roll level so that when a straightedge has chalk rubbed on the edge, the superfluous amount being blown off by the breath, and the straightedge placed carefully on the roll and rubbed lengthwise, the chalk will mark a line on the roll, touching at all places if the turning has been carefully done. The roll is then taken out of the lathe and the one to be turned with a curved surface put in the machine. The finished roll is placed in the carriage and put on top of the one in the lathe. The top roll carriage containing it is now moved 2⅝ inches to one side, (measured from the centre on the end of the roll in the lathe) and fastened in that position, the middle of the roll on top being put as close as possible to, but without touching the roll in the lathe.

The turning of it is now begun from the middle; cuts about 1½ inches wide being taken until the roll has a uniform concave surface, so that when the top roll still in its diagonal position is allowed to rest upon the bottom one, no light can be seen between them. It is then finished and ready for the mill. When newly turned rolls for making thin sheets such as tin plates are put in the mill, or are started on a Monday morning, it is necessary to bring them to their maximum temperature before wide sheets can be rolled. This is done by rolling narrow ones, until the rolls have expanded sufficiently to become level and make perfect plates.

Turning of sheet rolls is a tedious process, and attempts have been made

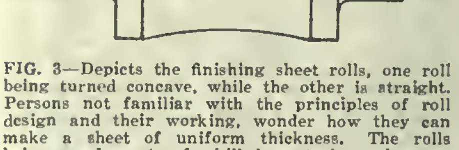

FIG. 3—Depicts the finishing sheet rolls, one roll being turned concave, while the other is straight. Persons not familiar with the principles of roll design and their working, wonder how they can make a sheet of uniform thickness. The rolls being made out of chilled cast iron, keep a smooth surface much longer than the ordinary cast iron ones. The use of chilled iron rolls for finishing sheets also saves money for the manufacturer and reduces the prices that the consumer pays.

to do this work by means of specially constructed grinding machines. This is a great success, both from an economical standpoint as well as a quality one, the work being done in one-half the time that it takes a roll turner to do it; while the rolls have a smoother finish and are more accurate in every respect. Sometimes a jam in the rolls will cause what is technically termed "a burnt spot." Its shape varies, depending upon the form of the material rolled. In sheet rolls it takes the form of a long streak of compressed chilled iron, extending parallel to the axis of the roll, its depth being about one-eighth of an inch.

Chilled cast iron is the hardest metal that the roll turner has to turn. The tool used to do the work is very little harder than the chilled iron, therefore in order to cut the metal at all, the roll has to revolve at a very slow speed, its periphery moving at a speed of one-half a revolution a minute. When a "burnt spot" is encountered, it being harder than the tool steel used to turn the roll, the edge of the tool breaks out and slides over the spot and refuses to cut. All the roll-turner can do when he discovers a burnt spot is to re-sharpen the tool, put it in the lathe and when the burnt spot nears, to take a very heavy cut so as to get under it and lift it out. When it is one-eighth of an inch deep, it has to be broken down a small amount at a time until it is finally removed. Doing this work is very tedious, and after it is done, the roll is made from ⅛ to ¼ of an inch smaller in diameter, the metal being wasted.

From the foregoing, it will be seen that it is necessary to turn a burnt spot entirely out of the roll in order to get a smooth surface, thus wasting time and money when a sheet roll is turned in the ordinary way. On the other hand, when a roll grinder is used, the emery wheels being very much harder than the metal in the roll, the burnt spot is easily ground with the rest of the roll's surface; only enough metal requiring to be removed to true and smooth up the roll.

The burnt spot being made smooth like the rest of the roll, it does not interfere with the making of good plates. Roll grinding machines are money savers and they are being used in increasing numbers. The writer knows of one mill where the rolls are necked in the usual manner, the necks being left 1-32 of an inch larger than the desired size, they being then ground to size in the roll grinder. This makes the rolls operate much better in the mill housings than when they are finished by means of a roll lathe. In conclusion, old locomotive tires can be made into other useful sections besides shovel and nail plates or for saws; the metal having such a uniform texture and excellence as to be made by the aid of rolls into quite a variety of shapes.

RENDERING CONCRETE-WEARING SURFACES NON-SLIPPING

Floor surfaces are usually rendered non-slipping by means of grooving, and many other forms of indentation, usually made by means of metal stamps or brass rollers, having studs or channels on their revolving surfaces. There are, however, occasions when these expedients are not possible, and it is then that the use of emery can be put to good advantage.

Emery is manufactured in various grades, but that known as flour emery is principally used for concrete steps and landings, while a granular form is used chiefly for gradient concrete surfaces.

It is quite unnecessary and wasteful to mix emery throughout the whole thickness of the concrete. Such surfaces are usually topped with at least one inch of granolithic concrete, through which the emery flour or coarser-grained emery is mixed. Steps, for the sake of appearance, are usually trowelled smooth; other surfaces may be left from the straightedge, although, should the occasion arise, granular emery may be sprinkled over the soft concrete surface, and slightly pressed in flush with trowel or handfloat. One pound of emery flour mixed with two parts granite, half pail of granite-sand, and one of cement, mixed thoroughly in the dry state before wetting, will, in an ordinary case, be successful.—M. E.

ANTI-FRICTION AND OTHER ALLOYS

At the meeting of the Allied Metals Congress held at Milwaukee October 7-12, a very practical paper was presented by Mr. H. M. Warring, Altoona, Pa., on the subject of the anti-friction and other alloys that have been adopted by the Pennsylvania Railroad and outlined some of the methods evolved by this company to hold their tin consumption to a minimum. The approximate composition of the non-ferrous alloys in general use by this railroad follows:

	Copper	Tin	Lead	Zinc	Antimony	Phos.
Phosphorus bronze	79.70	10.00	9.50	....	....	0.80
Ex. b. bronze	76.75	8.00	15.00	....	....	0.25
Car journal bronze	75.00	5.00	16.00	3.00	....	1.00
Special high-lead bronze	70.00	5.00	25.00	....	....	....
Lining metal	.....	....	.....	....	13.00	....
Dandelion metal	.....	10.00	72.00	....	18.00	....
Bell metal	83.33	16.67	.....	....	....	....
Babbit tin-base ..	3.70	88.90	.....	....	7.40	....
Babbit for motor bearings	1.00	50.00	38.50	....	10.50	....

Phosphor bronze is used principally for rod bushings, main rod brasses and cross-head shoes.

Ex. B. Bronze is used to a small extent for backs of car and coach bearings, but the majority of these are now made of car journal bronze which contains on the average about 5 per cent. of tin.

Car journal bronze is used for making car and coach bearing backs, by melting down the old backs after removing the linings and making the necessary addition of new metal to bring the composition within the limits given above. No new tin is added in making this alloy.

Formerly the lead-base linings of car bearings was melted off and brought up to requirements by additions of new metal as required, but lately as this metal contains some tin, it has been used in making dandelion metal, thereby conserving the tin content. The lining metal is then made from new lead and antimony and contains no tin. Dandelion metal contains about 10 per cent. tin and is ued for lining cross-head shoes, engine truck and trailer bearings, hub liners and so forth, and its use has eliminated a large amount of tin-base babbitt.

Bell metal is used for locomotive bells, and during 1917 about 21 tons of this type of casting were made, involving the use of slightly above three and a half tons of tin.

The use of tin-base babbitt has been greatly restricted and every effort is being made to replace it with lead-base babbitt.

The amount of solder containing 50% tin and 50% lead was a big item, but the bulk of this has been changed to 40% tin and 60% lead, making a considerable saving in tin.

Another practical paper was presented by M. L. Lissberger on the subject of tin economy in solders. The method adopted by his firm in making solders is to first melt the lead, then add a flux and skim the dross, after which the tin is added. After this addition the bath of molten metal is stirred continuously for from five to six hours to thoroughly incorporate the metals, because if this is not done, trouble from segregation will ensue owing to the fact that tin and lead do not form alloys, but exist together as a mechanical mixture. It is therefore necessary to thoroughly break up the droplets of metal to enable those of the two metals to come into intimate contact and thus produce a more homogeneous mixture than is otherwise possible This segregation is illustrated by what occurs when a block of solder one inch square and six inches high is cast. An analysis taken from the bottom will show 47 per cent. tin and 53 per cent. lead, and from the top 53 per cent. tin and 47 per cent. lead, when the metals have been thoroughly mixed. This illustrates why so much more tin than lead is lost in making solders by drossing. The alloy from which the above example is taken is composed of 50 per cent. tin and 50 per cent. lead. For solders used as a filling metal and not as a cement, tin can be conserved by using an alloy of 20 per cent. tin and 80 per cent. lead. For adhesive purposes and especially for food containers, a solder containing 40 per cent. tin and 60 per cent. lead can be recommended. For making solders, overheating must be avoided with the utmost care, otherwise much tin will be lost on account of the excessive dross that will be formed, and as this dross is always richer in tin than in lead, it will be evident that the alloy itself is impoverished in tin, and much of this metal is wasted unnecessarily.

An excellent solder consists of in 46 per cent. and lead 54 per cent., with a small amount of antimony, say about 0.25 per cent., which improves its appearance.

A storage battery electric locomotive, invented in Switzerland, for switching, uses powerful electromagnets instead of couplings for drawing cars.

Testing Machines in Industrial Laboratories—II

The Wise Purchasing of Engineering Materials is Dependent Upon Specifications Properly Controlled by Analysis and Test

By H. S. PRIMROSE, Messrs. Crittal Mfg. Co.
and J. S. GLEN PRIMROSE, Messrs. Ransomes & Napier, Ltd.

THE various forms of impact and pressure machines for determining the values of hardness of metals are now well known, and serve the useful purpose of being able to connect by a simple factor the hardness value with a close approximation to the tensile strength of the material. Table III gives a useful list of equations connecting the tensile strength in tons per square inch of various steels, both alloy and plain carbon, with their hardness on the Brinell and the Shore scleroscope scales, as also the relation which exists between these two scales for the steels concerned.

TABLE III—Equations connecting the Tensile Strength in Tons per Square Inch with the Hardness of various Steels on the Brinell and Scleroscope Scales, also the two Scales with one another.

Steel.	T.S. from Brinell No. "B."	T.S. from Scleroscope, Value, "S."	Brinell No. from Scleroscope.
Carbon	0.325B—12.5	1.96S—12.5	5.6S+0.14
Nickel	0.318B—14.3	1.56S— 2.7	5.0S+0.48
Chrome-Vanadium	0.318B—12.9	1.87S— 9.4	5.5S+0.27
Low Chrome Nickel	0.304B— 9.8	1.65S— 0.45	5.4S+0.33
High Chrome Nickel	0.318B—14.7	1.05S— 1.34	4.8S+0.58
Average	0.312B—11.6	1.80S— 6.7	5.5S+0.28

One method of performing the Brinell test is by the insertion of a special carrier in the crown of the Amsler testing machine and bringing up the pressure to the required amount on the test-piece, measuring its value on the dial scale (Fig. 8). The diameter of the impression may be read with sufficient accuracy by means of a transparent taper scale, and the corresponding hardness value in kilogrammes per square millimetre may be derived from a graph made on logarithmically-squared paper to save the use of long tables of figures.

Instead of the diameter, the size of which is sometimes doubtful in the case of soft metals, it is often preferable to measure the depth of the Brinell ball imprint to get the area of the cavity in terms of the product 3.1416 D t, where D is the ball diameter and t the impression depth, both in millimetres. Messrs. Amsler Brothers have a very neat form of depth indicator which may be inserted in their compression machine in the same way as the ordinary bolster carrying the plain ball. In this case the ball is held in a somewhat longer chuck, which passes through te body of the depth-measuring instrument made of bronze and provided with a collar carryiny a very fine screw thread on the outside, and engaging the ball chuck by friction. The outer body of the instrument bearing the scale graduated n twentieths of a millimetre supports a ball-and-socket ring loosely held by three screws, and any motion of the ball chuck relative to the frame pushes open a retaining spring, lowers the finelv-threaded screw collar, and rotates a pointer over the graduated scale. The method of operation is exceedingly simple, and the zero adjustment can be quickly and accurately performed. The smooth metal surface of the specimen to be tested is raised by the support in the cradle until it engages the 10 mm. steel ball, then the body of the instrument is slipped down on the chuck till the ring rests on the test-piece. By pulling out the disengaging handle to the left, the pointer swings loose, and can be brought near to the zero mark before again engaging the screw. If the pointer still misses the zero mark, the milled head of the screw can be rotated slightly to make the coincidence exact. The desired load is next applied, and the ball, entering the metal under pressure, carries the pointer over the scale to a point indicating the depth of penetration. Elastic deformation must be allowed for by releasing the load to all but about 20 lb., and then reading the correct depth. The construction of this compact instrument is shown in the diagram, Fig. 8.

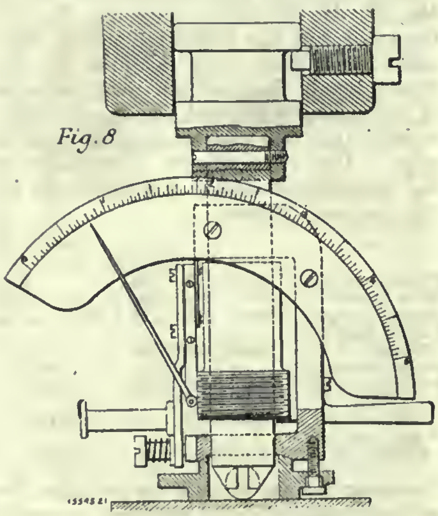

FIG. 8

A more recent form of the same type of depth indicator made by the firm of Amsler Brothers is shown in Fig. 9, which illustrates the application of the same principle in the determination of hardness by means of the 90 deg. angle Ludwik cone. The knurled ring surrounding the cone rests with it at the same level on the smooth surface of the test specimen. When the cone, under pressure, enters the metal, the knurled ring remains on the surface and pushes back the outer frame of the instrument and thus rotates the pointer over the scale, each division of which represents a depth of penetration of one-hundredth of a millimetre.

Guillery Hardness Testing Machine

A very useful form of portable hardness-testing machine, the results from which can be arrived at without any measurement or calculation, is that designed by R. Guillery and made by Messrs. Malicet and Blin, of Aubervilliers, France. The simplicity of construction is readily seen from the illustrations of the machine given in Figs. 10 and 11. The iron frame A contains in its lower part a powerful spring R which is made up of a number of discs forming a Belleville spring. This is accurately standardized to give a pressure of 3,000 kg. to a plate Q carried on the central rod B passing through the spring, and this rod rests on the knife edge C. The forward movement of the hand lever G causes the cam to raise the bent lever D about its fulcrum and apply the load. The milled head I serves to rotate the screw V bv friction, but this slips round immediately the hardened steel ball H, clipped securely to the screw, comes into intimate contact with the test-piece placed on the supporting plate Q. The semi-circular scale M is attached to the upper part of the frame, and the pointer L is carried by slight friction on the plate J, which rotates with the screw V. In working the machine, the hand lever is first put back into the rear position, and the test-piece is lightly gripped between the ball and the supporting plate by advancing the screw by means of the milled head until slipping takes place and the screw ceases to move. Then the pointer is brought over the zero mark of the scale. the hand lever is brought forward to the front position, where it remains without being held for the required time, and it is then put back into its first position. In this way the ball comes out of the impression it has made and the screw is again free to advance and engage the surface of the metal in the indentation. The driving head I is therefore rotated until the screw goes no further and slipping occurs. This operation carries the pointer over the graduated scale to the same angle that the screw has turned, and for soft metals this operation of applying the pressure and advancing the screw is repeated till the screw will advance no further. This then measures the depth of the imprint, but the graduations on the scale are so arranged that it is not the actual depth which it indicated, but the corresponding Brinell hardness number. The sole precaution needed is to ensure that intimate metallic contact exists between the ball and the test-piece, since any scale will spoil the correctness of the reading, which is ordinarily quite sufficiently accurate for commercial purposes. The hardness value can always be checked by measuring the diameter of the imprint in the usual way. A large size of this type of hardness tester has recently been brought out by Guillery, but as it works in the horizontal direction it readily enables the largest shells to be tested for hardness in any side position across a diameter. A sectional view of this machine is given in Fig. 12.

Impact-Testing Machines

The importance of the impact test is gradually coming to be more widely recognized, and a valuable impulse to its adoption has been given by the latest results of the Committee of the International Association for Testing Materials, which were published recently by Charpy. He tested several different types of machine, which, although working on such different principles as the drop-weight, the swinging pendulum, and the rotating flywheel, yet were found to give strictly comparable results, and these were found to be quite independent of the weight and speed of the tup used, and also of the weight of anvil used, provided, of course, that the steel used is thoroughly normalized, and that the method of holding the test specimen was not objectionable, but merely resting in its place.

The swinging pendulum type approved by the International Association is well known, but the Amsler vertical drop-weight machine mentioned by Charpy is less well known, and has recently been superseded by a new form of swinging hammer. This is shown in side view in Fig. 13, and consists of a heavy cast-iron base to which are bolted two upright channels supporting the pendulum and the elevating winch which can raise the pendulum either to left or right, depending upon how the detachable hook is attached. On falling from the left side the weight breaks the test-piece transversely and when falling from the right, tensile impact tests are made. A friction clutch holds the swinging arm in any desired position as the windlass raises the bob weight, and the operating handle cannot be moved by the weight itself, but only by the operator. On pulling the release cord, the hook is detached and the trip falls freely, and after breaking the bar it swings up on the other side of the machine. Instead of swinging back, however, it is held in its position of maximum height by a third cord passing round a drum and acting as a brake. The circular weight at the end of this cord exerts a sufficient pull to prevent the pendulum from falling back from any position until it is released. To measure the energy absorbed by a blow of the pendulum the difference is noted between the readings of two scales provided on the vertical supports. The elevation of the weight moves a pointer over the first scale to show the energy stored before the blow, and the swing of the pendulum carries another pointer over a second scale to indicate the residual amount of energy after the blow. The change over from transverse impact to tensile impact test is readily accomplished by unhooking the elevating cord from one side of the tup and fixing it to the other side, then the windlass is

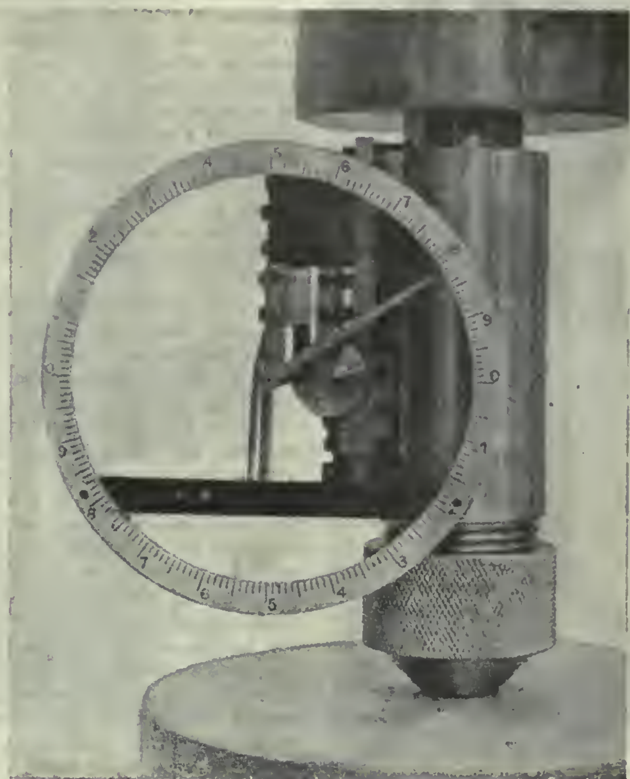

FIG. 9—MACHINE FOR DETERMINING HARDNESS BY 90 DEG. LUDWICK CONE.

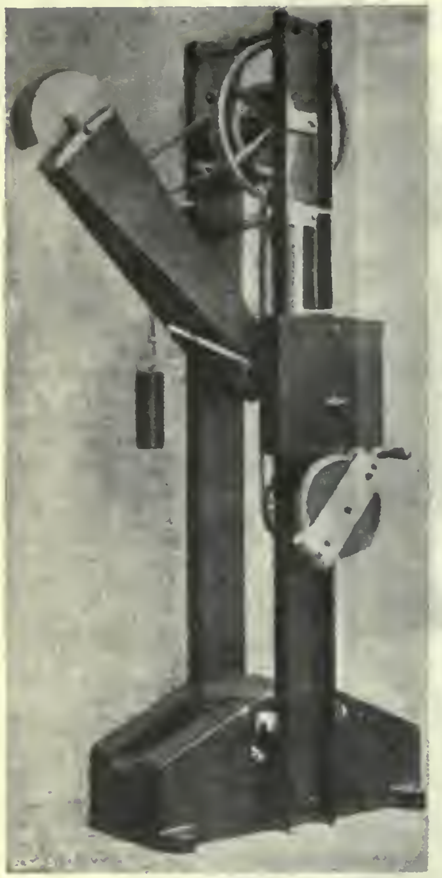

FIG. 13—AMSLER SWINGING-HAMMER

wound up by turning the handle in the opposite direction from before.

Guillery Impact-Testing Machines

The most convenient type of impact tester for works practice which entails the minimum of effort and calculation, is the rotary dynamometer tup or rotating flywheel made by Malicet and Blin to the design of M. Guillery. The latest form of this machine consists of a flywheel of such shape and size that when rotating at 302 r.p.m. the velocity of the striking knife is the same as that of a body falling freely from a height of 4 m. (say 29 ft. per second). The moment of inertia of the wheel is such that when hunning at this speed, the energy stored in it is 60 m.-kg. for the one size, and 275 m.-kg. for the heavier type of wheel approximately 440 ft.-lb. and 2,000 ft.-lb. respectively. The lighter machine may be compared to a falling tup or "monkey" of 15 kg. weight falling from various heights up to 4 m., and these are registered by one of the speedometer scales. It is usual to work up to the highest reading and capacity of the machine, and for this reason the scale for measuring the energy absorbed in the blow has its zero at the top of the tube. The flywheel of the machine is made to rotate by a handle connected with an adjacent lever which, according to its position either puts the handle into gear for speeding up, or disengages to allow the wheel to run free. A third position applies a brake to stop the rotation of the wheel when the tests are completed. The connection between handle and wheel can be made readily when the wheel is in motion. An ingenious device throws the handle out of gear if it is attempted to turn the wheel in the wrong direction. The equivalent height of drop and the energy absorbed by the impact are read on the tachometer tube, the scale of which gives the highest reading when the wheel is at rest and adjusted to coincide with the 60 m.-kg. mark by means of a milled screw. This moves up or down a float inside the centrifugal pump shown in Figs. 14 and 15, and the vanes of this (rotated by bevel wheel from the axis of the flywheel) serve to raise a colored liquid in the speedometer tube.

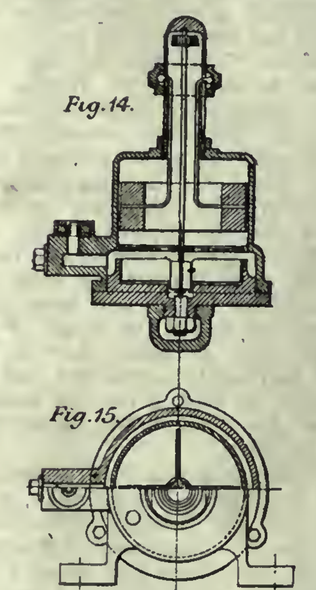
A view of the machine taken with the cast-iron top cover removed from the lower casing and pedestal, shows in Fig. 16 the simple mechanism whereby the breaking knife is attached to the flywheel, so that when in the closed, or "in" position, the knife is completely encased within the rim of the flywheel. When the red stud is pressed, the spring forces the knife into the open or "out" position required for breaking the test bar. The knife is made to assume these positions by means of the rotation of the flywheel itself, according as the closing or opening button is pressed on the outside of the lower casing. In working the machine, it is only necessary to restore the energy lost in each test to make the machine ready for the next test. The danger of the open knife is obviated by a simple device which prevents the door (enclosing the test bar when in position) from being opened so long as the knife is out and the flywheel still rotating. The small and safe design of this machine, in which all the moving parts are enclosed, the lack of overhang and stability even without bolting down, so long as it rests on a level floor, and the direct reading of the energy absorbed, makes this machine one of the most simple and advantageous to use.

Table IV gives the results of several samples of mild steel which had proved brittle in working and which gave low impact values. A replace material, although similar in other physical properties behaved well in service, and, on testing in the impact machine, showed much better results. The effect of heat treatment on some medium carbon steel as regards impact values is also shown in an interesting fashion.

Repeated Impact-Testing Machines

One of the simplest forms of repeated impact-testing machines recently introduced, to avoid the chattering sometimes met with, is the Eden-Foster machine, which is made in this country. A cam operates a lifting chain to engage a small vertical drop hammer, which is only released when the lifting mechanism is lowered to be clear of the fall. Two different weights of tup are used, and the whole apparatus is small and compact, although capable of taking the standard notched bar for this test. The bar is rotated in a simple friction clutch method whilst securely held in two plummer blocks.

A different principle is used in the quadruple hammer machine for repeated shock testing, as made by Messrs. Amsler Brothers. The bar to be tested is supported at the two ends, and a pair



FIGS. 14 AND 15—PUMP FOR GUILLERY MACHINE

of hammers deal it blows alternately from right and left until it breaks. The fracture is thus produced by fatigue. At the moment of fracture of the bar, the mechanism actuating the hammers is thrown out of gear and the blows cease. A counter indicates the number of blows received by the bar before fracture. The machine as shown in Fig. 17 consists of four pairs of hammers working simultaneously upon four bars. The hammers receive their motion from a single shaft.

driven by a small electric motor. The pairs of hammers are quite independent of each other, and when one pair stops owing to the fracture of the bar, the other pairs continue their movement, so that the different bars are tested quite independently. The bars are cylindrical independently. The bars are cylindrical in shape, and 12 mm. in diameter, from 18 cm. to 19 c.m. long, as their supports are 17 mm. apart. These supports can turn on a vertical axis, which permits the bars to be bent freely by each blow, so that they do not behave like tightly-gripped bars. The blow of the hammers is delivered at two diametrically opposite points. The weight of each hammer is 5 kg., and they fall freely through a vertical height of 5 cm., so that each blow expends ¼ m.-kg. of energy on the bar. The counters record the number of rotations of the shaft, and thus the pairs of blows struck. The usual speed of rotation is about 90 r.p.m.

FIG. 16—GUILLERY IMPACT-TESTING MACHINE

BRITISH ADMIRALTY APPRECIATES MERCHANT SERVICE

On the occasion of the first meeting of the Board of Admiralty after the signing of the German armistice their Lordships desire, on behalf of the Royal Navy, to express their admiration and thanks to the owners, masters, officers, and crews of the British Mercantile Marine, and to those engaged in the fishing industry, for the incomparable services which they have rendered during the war, making possible and complete the victory which is now being celebrated.

The work of the Mercantile Marine has been inseparably connected with that of the Royal Navy, and without the loyal co-operation of the former the enemy's submarine campaign must inevitably have achieved its object. The Mercantile Marine from the beginning met this unprecedented form of warfare with indomitable courage, magnificent endurance, and a total disregard of danger and death, factors which the enemy had failed to take into account and which went far towards defeating his object.

In no small measure also has the success achieved against the submarine been due to the interest taken by owners in the defensive equipment of their ships, and to the ability, loyalty, and technical skill displayed by masters and officers in carrying out Admiralty regulations, which, though tending to the safety of the vessels from submarine risks, enormously increased the strain and anxiety of navigation. The loyal observance of these precautions has been the morec ommendable since the need for absolute secrecy, on which safety largely depended, has prevented the reasons for their adoption being in all cases disclosed.

Further, the convoy system, which has played such an important part in frustrating the designs of the enemy and securing the safe passage of the United States Army, could never have attained its success but for the ability and endurance displayed by the masters, officers, and crews of the merchant ships forming these convoys. This system has called for the learning and practising of a new science—that of station-keeping, the accuracy of which has depended in no small measure on the adaptability and skill of the engineers and their departments.

Their Lordships also desire to acknowledge the ready response of owners to the heavy calls made on the Merchant Service for officers and men to meet the increasing requirements of the Navy. On board our ships of every type, from the largest dreadnought down to the smallest patrol boat, are to be found officers and men of the Merchant Navy, who have combined with those of the Royal Navy in fighting the enemy and defeating his nefarious methods of warfare at sea.

The Merchant Service and the Royal Navy have never been so closely brought together as during this war. In the interests of our glorious Empire this conclusion must prove a lasting one.

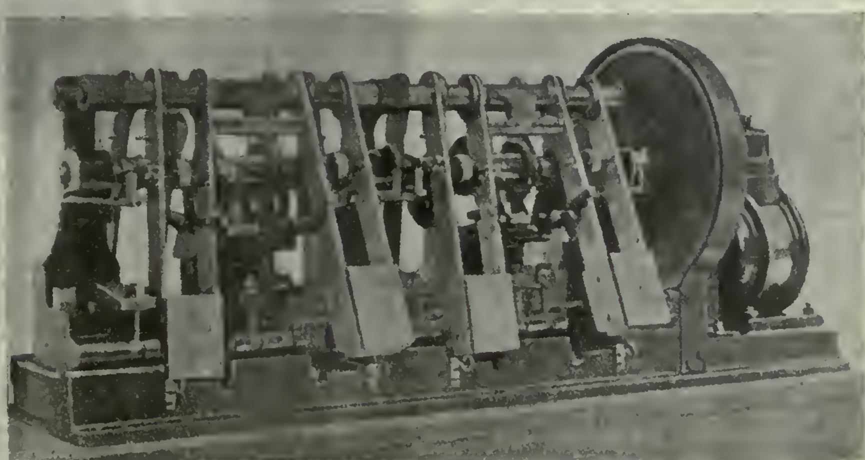

FIG. 17—AMSLER QUADRUPLE-HAMMER MACHINE FOR REPEATED SHOCK TESTING

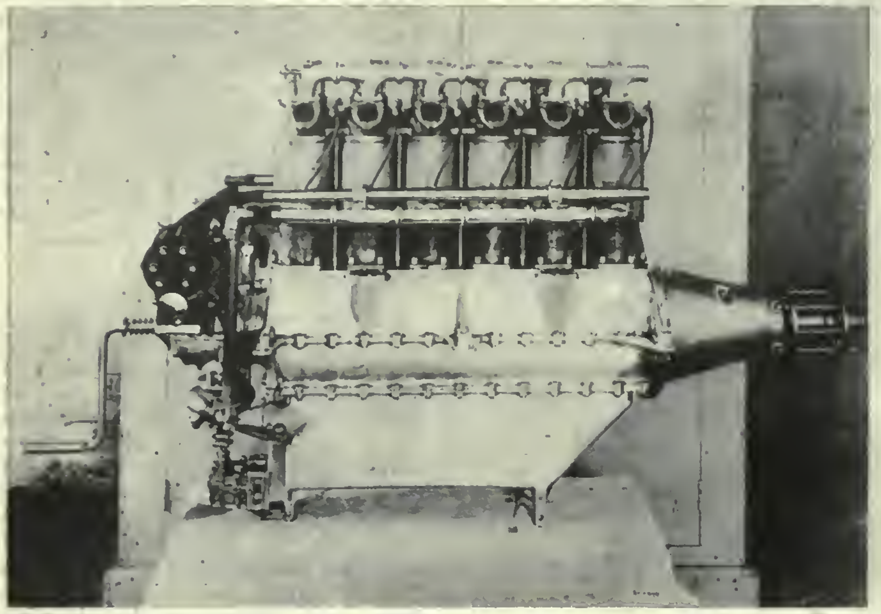
The Greenfield Tap and Die Corporation, Greenfield, Mass., have issued catalogue 40 on small tools. As its name indicates, the tools featured are taps, dies, screw plates, reamers, and other tools of like nature. The screw plate section describes all the various plates made by the firm for every purpose, including automobile and metric sizes. Hand taps are described in detail, the gun tap being particularly worthy of mention. Nut taps, tapper taps, pulley taps, and other kinds are described at some length. The reamer section contains information concerning the various lines of reamers manufactured by the corporation, and the data section contains much material of value bearing on threads and thread cutting. Much of this is new and has to do with the gauging of threads.

AEROMARINE 6-CYLINDER VERTICAL MOTOR

By F.C.P.

The accompanying illustration shows a novel aeromarine 6-cylinder vertical motor of which the reciprocating and revolving parts are made of steel and the upper and lower parts of crank case are made of composition aluminum casting.



AMERICAN SIX-CYLINDER AEROPLANE MOTOR

The oil reservoir in the lower half casting provides sufficient oil capacity for five hours continuous running at full power and increased capacity is provided to meet greater endurance requirements.

As to the oiling system it may be stated that the oil is forced under pressure to all bearings by means of high pressure duplex geared pumps. One side of this pump delivers oil under pressure to all the bearings while the other side draws the oil from the splash case and delivers it to the main sump. The oil reservoir is entirely separate from the crank case chamber. Under no circumstances will oil flood the cylinder and the oiling system is not affected in any way by any angle of flight or position of motor. An oil pressure gauge is placed on instrument board of machine which gives at all times the pressure in oil system and a sight glass at lower half of case indicates the amount of oil contained. It is held that the old style system of dropping lower half of crank case to clean strainers and inspect pumps is avoided and the oil pump is external on magneto end of motor and is very accessible. There is provided an external oil strainer which is removable in a few minutes' time without the loss of any oil. All oil from reservoir to the motor passes through this strainer. Pressure gauge feed is also attached and can be piped to part of machine desired.

The water jackets are of copper 1/16" thick electrically deposited. This makes a non-corrosive metal. The cooling is furnished by a centrifugal pump which delivers 25 gallons per minute 1400 R.P.M. The pistons are made cast iron, accurately machined and ground to exact dimensions, which are carefully balanced.

The intake manifold for carburetors are aluminum castings so designed that each carburetor feeds three cylinders thereby insuring easy flow of vapor at all speeds. The power developed is 85-90 h.p. and the weight of the motor is four hundred and twenty pounds. The data of a horsepower test on one of these 6-cylinder motors as given in the following for an engine with 4 5/16" bore x 5⅛" stroke may be of interst:

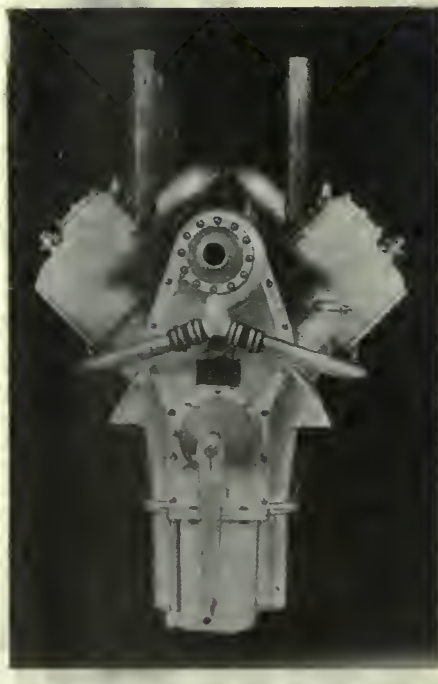
Fan-blade	Revs. per min.	Pull in lbs.	h.p.
D	1830	52.	95.16
C	1700	56.5	96.0
B	1510	58.5	88.33
A	1350	62.	83.7
0	1140	62.	70.68
00	1040	60.	62.4
000	960	57.	54.7

The average gasoline consumption for the aeromarine motor is 53.96 lbs. per hour and 8.55 gals. per hour are used which makes 0.63 lbs. or .104 gals. per h.p. hour. The average oil consumption of this engine is 1.75 gals. oil used per hour or .02 gals. oil per h.p. hour, which figures out 12.3 lbs. per hour and .144 lbs. per h.p. hour.

TUNGSTEN FILAMENTS

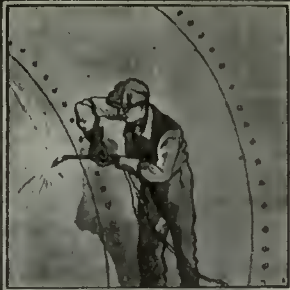
A new lamp filament patented in Germany recently consists of a single long crystal of tungsten instead of the usual irregular string of crystals and has in consequence greatly increased strength and durability. The ordinary filament is produced either by hammering fine tungsten powder into lumps, and drawing or rolling, or by squirting a mixture of the powder with a binding material and then sintering. In the new process very finely divided tungsten acid is freed from its oxygen by heating in an atmosphere of hydrogen; the powdered metal so produced is mixed with a definite quantity of therium oxide and a small amount of a colloidal binder; the paste is squirted under pressure through fine dies; and the filaments, after gentle drying, are finally passed through a forming or structure changing apparatus. This apparatus is a glass cylinder, closed and air-tight at top and bottom, containing a spiral of several turns of tungsten wire heated by electric current. In a stream of reducing gas eight filaments at a time are passed at the rate of about 8 ft. an hour, and the sudden and continued heating to 2,600° or 2,700° C., has the effect, as shown by the microscope, of joining the large number of crystals of each filament into one long crystal. In tests of 1,200 hours the filaments have shown no change, retaining great strength and freedom from cracks on bending, with no blackening of the lamp bulbs.—M. M.

W. F. Keckeisen, formerly advertising manager of the International Filter Co., and previously associated with the Federal Sign Co., has joined the staff of Russell T. Gray, advertising engineer, Chicago.



END VIEW OF ENGINE

Opening Branch:—The Independent Pneumatic Tool Company announces the opening of a Branch Office and Service Station in Cleveland, Ohio, on December 15th. A complete line of Thor Pneumatic and Electric Tools and Repair Parts will be carried in stock at 1103 Citizens Building, under the management of Mr. Hayden F. White, who has represented the company in Detroit, Chicago and Milwaukee districts for some years past.



WELDING AND CUTTING

The Steel Ship and Oxy-Acetylene Welding

The Author, in "International Marine Engineering," Makes Some Valuable Observations on the Behavior of Metals Under the Welding Flame, and the Precautions to be Observed

By J. F. SPRINGER

THE present necessity to construct quickly a vast total of tonnage has doubtless been the chief thing that has brought the newer methods of welding so prominently to the attention of shipbuilders and the Government. The oxy-acetylene process has been winning its way steadily for the past decade, particularly in connection with steel plates. I direct attention to steel cylinders used in the transportation of gases under pressure and to steel barrels employed as containers liable to rough handling. The welding work here is analogous to that required in a ship's side.

However, not all operators of the torch understand what happens to the steel and what are the possibilities of restoring any damage to the quality incident upon the application of gas and electric welding. A good many are probably ignorant that there is any damage to quality that needs rectification. Let us then consider this matter.

Behaviour of Steel When Heated

All normal, unhardened steel consists of crystals or grains built up of alternate laminations of cementite (Fe.3C) and iron, with or without separating films either of iron or of cementite. In steels containing less than 0.85 or 0.90 per cent of carbon—such as are practically all steels used for ship plates—there is a honeycomb of pure iron. The spaces or cells in the honeycomb are occupied by crystals, or grains of interleaved layers of iron and cementite. Steels containing a higher carbon percentage—tool steels—have a honeycomb of cementite; the crystals are the same as before. For steel at the dividing percentage, there is no honeycomb; the crystals are the same, but they are now in actual contact. The interleaved layers of pure iron and cementite constitute a material (it is not a chemical combination, being non-homogeneous), which has been named pearlite by Professor Henry M. Howe, of Columbia University. For ship construction, steel having the first type of structure—a honeycomb of pure iron filled with pearlite crystals—is used.

Behaviour of Crystals During Heating

The importance of this information in connection with oxy-acetylene welding centers on the behaviour of the crystals of pearlite during a rise of temperature. As the temperature rises from the normal, everyday point, nothing of importance occurs until the steel has passed above a black heat. About medium cherry red (1,274 degrees Fahr.), the grains begin to grow. As the temperature goes on up, the grain size continues to increase. Probably there is no substantial cessation of growth until the steel is at or near the melting point. If the heating is halted at any point of temperature, the growth will also halt. When the steel is cooled, whether suddenly or slowly, the enlarged grain size will still persist. Now all of this is not merely something interesting, but important practically, for the reason that cold steel with big grains is steel in an inferior condition. Its tensile strength is less than normal. Further, we are to accept it as a fact that the bigger the grains the weaker the steel. As cooling off does not restore the normal, small size and high strength, it will be readily understood why oxy-acetylene welding and similar processes (inclusive of blacksmith welding) necessarily injure the steel. These processes must use high temperatures. It is not in the gas processes, merely, that the working flame is at a very high temperature; the work itself becomes highly heated, the temperature ranging from at or near the melting point to lower temperatures as one recedes from the beveled edges and away from the groove. In the groove, every particle of the new metal has been actually melted. Of course, there has been great enlargement of the grain size. The metal must be regarded as greatly inferior in strength to the same metal when in normal condition. This applies to the new metal in the groove, to the sides of the groove and to the metal back from the groove. Every spot where the temperature has risen above medium cherry red must be viewed as damaged in strength.

Protection Against Oxidation

This is not a question of the burnt metal. Burnt steel is afflicted with a different disease. When steel is actually burnt, the carbon has been consumed. It is the procedure of burning steel that is employed in cutting with a high-pressure oxygen jet. By this process an oxy-acetylene or other heating jet is used to heat up the metal and the oxygen jet follows it very closely. The oxygen attacks the carbon and burns it. The welding operation with the oxy-acetylene flame may, however, be very well protected against oxidation. Considering the fact that oxidation might result from the oxygen passing through the torch, a proper adjustment of the flame to a neutral condition should cover the matter pretty fairly. Nevertheless, it is quite customary with many welders to use some very pure iron for the new metal. As this iron contains little or no carbon, it is but little subject to burning. In so far as oxidation from the atmosphere is concerned, the torch may generally be managed so as to utilize the large flame, which envelops the little working flame, as a protection. It is, from its very nature, a reducing flame and consequently adapted to this purpose.

Account of a Curative Procedure

In seeking to use the oxy-acetylene procedure in welding ships' plates, it is probable that a damage from oxidation could be provided against with a good deal of success by methods such as those just indicated. With this damage eliminated, however, we would still have the deterioration attendant upon the enlargement of the grain size. If the welding of ships' seams is to be a success, this deterioration must either be cured or offset. Piling up the new metal is a method of offsetting. I now proceed to give some account of a curative procedure.

If steel that has had its grains enlarged by overheating be cooled off to any point distinctly below medium cherry red (1,274 degrees Fahr.) and then reheated, its grains will begin to break up and assume a smaller size at a point of temperature at or a trifle above medium cherry red. This is understood to be a pretty well ascertained scientific fact. If the steel contains about 0.85 or 0.90 per cent. of carbon and, consequently, no honeycomb either of pure iron or of cementite, then this method is understood to yield very perfect results. Indeed, down to 0.50 or 0.40 per cent. carbon steel, the method is to be regarded as quite good indeed. The stopping point on reheating, however, rises somewhat above medium cherry red. Below 0.40 per cent. carbon steel the method is less perfect, because a compromise has to be made between carrying the heat up a bit and having a resizing of the grains that is less than complete. There is, then, a known procedure for the restoration of the quality of the steel. This method, as indicated, requires that the work be reheated after the welding is completed.

A second curative procedure may be mentioned, though it is perhaps not so successful in the generality of cases. It has long been known that working steel under the blacksmith's hammer has a beneficial effect. It did not require the new developments in connection with the microscopic study of steel to reveal this broad fact. What has been uncovered of late years is a more precise knowledge of the proper "stopping points." Probably, steel that is going to be thoroughly worked may be subjected to working at pretty high temperatures, provided the "stopping point" is well chosen and the working is continuous from start to finish. The grain size will then be somewhat larger than that which corresponds to the stopping temperature. In short, the hammer or other device will break up the grains; but the prevailing temperature is also getting in its work.

Professor Bradley Stoughton Quoted

Oxy-acetylene welders have sought to get the benefit of working by using the hammer on the weld. Probably it does some good, provided the hammering is not continued until too cool a point is reached. Let me quote from Professor Bradley Stoughton.

"Mechanical work will multiply the strength of steel from two to five times. In order to accomplish as much as this latter, however, it is necessary (1) to reduce the material to very small sizes in order that the beneficial effect of the kneading action may extend throughout the mass, and (2) to finish the work cold, in order that the metal may have no opportunity to re-crystallize. The ductility also will be increased at first by working, but again decreases if the metal is worked cold. The increase in strength and ductility is due (1) to decreasing the size of the crystals and closing the grain of the steel; . . . (3) to increasing the cohesion and adhesion of the crystals. All these effects increase the specific gravity and hardness of the metal, and are more effective in these respects, as well as in increasing strength, if hot work is followed by cold work."

Restoration of Lost Strength

It is doubtful whether in the oxy-acetylene process full compliance can ever be given to the above requirement for a thorough kneading throughout the mass. Consider a longitudinal seam between two plates in a ship's side. Since the plates have been rolled in the process of manufacture their normal strength presumably includes a decided advance on the strength of unworked steel. In fact, the high strength of the rolled plate was undoubtedly figured on in designing the ship. The process of autogenous welding materially decreases this strength because it undoes about everything that the rolling had previously accomplished. We seek to restore the lost strength by the use of the hammer. It would seem to be difficult, if not impossible, to reproduce with the hammer the condition which the rolling mill originally produced. Still, many difficult problems have been solved—this may be the next. Some mechanical device may be devised to work the metal in, and along the seam to an extent equivalent to that accomplished with the rolling mill—some device which will secure penetration of its effects and will cover all regions involved in the high heat. Such an advance in the development of the oxy-acetylene process would not be anything very radical, since machine welding and cutting have both been done for quite a number of years. Wherever a machine can be used either for welding or cutting, better work can probably be done as mechanical methods automatically secure evenness and regularity. Long straight seams, such as those on a ship's side, are particularly well suited to machine welding methods. It would seem, then, that a machine forger or kneader might very well handle this same class of work. Several years ago the present writer gave an account of European machines for the welding up of plate steel to form tubes. This process is very similar to the welding of ship plates. But I do not known of any machine which is especially adapted to work the steel after the welding operation.

One trouble with the hammer is the lack of penetration. "A blow creates in a metal practically nothing but compressive strains, which act chiefly in the vertical direction, and, by transmission, in the two horizontal directions. Because the pressure is relieved almost as soon as felt, the elasticity of the metal causes it to recover somewhat from the effect. This makes the effect of hammering superficial. Also the amount of yield to it is not great in proportion to it is not great in proportion to its force, and therefore it takes more pressure to accomplish a result than would be the case if the application were slower. This makes hammering a slow process of reduction, but results in a better and more uniform working of the crystals on the surface at least, which is one of the chief reasons for the superiority of hammered over rolled material. Another reason, perhaps even more potent, is the exact control of the operation which can be exercised by the expert forger, especially his control over the temperature at which the work is finished, and over the varying forces of pressure applied at different stages and temperatures. On the other hand, the effect of forging extends only skin-deep from the upper and lower surfaces."*

Cold Drawing to Improve Strength

Perhaps a mechanical device could be produced which would exert an action superior to that of the hammer and more like that of the rolls in a rolling mill. It is quite probable, too, that the requirement mentioned in the preceding excerpt, which calls for cold working, can be more adequately and safely met by mechanical means. This is especially true if semi-skilled labor is employed. With a machine the regulation may be exact and uniform, insuring continuous movement of the steel particles, although small for any one moment. For example, cold drawing would be a very effective means of improving the strength of the material. Tremendous pressure, however, would have to be exerted in this process.

It will be easily gathered from the foregoing that the simple hammering indulged in by a lot of oxy-acetylene welders can be counted on but slightly. In the hands of a skilled welder who understands the thing at which he is aiming and the way to get it best with such a tool, the hammer is doubtless a good thing and the work will probably be better for it. This is saying less, however, than that a full restoration can be thus accomplished or even approximated. In the hands of an ordinary oxy-acetylene welder, the hammer's usefulness would appear to be greatly limited.

After all is said and done, the reheating method appears to be the better thing. It is all-penetrating, seeking out the regions adjacent to the weld and also regions inside the mass. It is not, or at least need not be, superficial in its action thus surpassing the hammer. Furthermore, heat is easily applied. In the first place, we have as a convenient source of heat the enveloping flame which surrounds the little white working flame. The temperature of this flame is not excessive—like that of the white flame—besides, it is safe, because of its character as a reducing agent. It has a great appetite for oxygen, so that it may be depended upon not only to bring oxygen to the heated metal, but even to protect it from outside oxygen. Oxy-acetylene welders have been using this enveloping flame as a means of treating the weld, but that they have generally done so intelligently I am not prepared to vouch. The re-heating process, as has already been explained, gets its restorative results by heating up from a temperature point below medium cherry red (1,274 degrees Fahr.). This is to be regarded as essential. It is not enough simply to wave the big enveloping flame over the newly welded work. Attention must be directed to starting the heat from a sufficiently low point—a cooling off must be accomplished first of all. It does not matter how cold the work is allowed to get. It may be a black heat or it may be stone cold. The point is to get it below 1,274 degrees. Naturally, in this re-heating procedure it is cheaper to heat up from a black heat than from a stone cold condition.

Action of the Enveloping Flame

But this re-heating does not have to be done with the big enveloping flame. This flame is a good one, especially since it has a reducing quality; but it is quite expensive, particularly in the present case. Sometimes there are uses for the enveloping flame which are advantageous and economical. This flame may at times be so managed as to provide a means of pre-heating without interfering with the simultaneous employment of the white working flame. When this can be done, the enveloping flame heats the work up through the early stages, thus relieving the white flame to this extent. To put this idea into use on steel plates in a ship's side, the torch might be controlled in a frame or bracket in such a way as to compel half of the enveloping flame to lie along the seam ahead of the white flame. The Edison Storage Battery Company has so used the oxy-acetylene torch in welding the vertical seam in the sheet steel containers which constitute part of a storage battery cell. The torch is held at a fixed angle by a holding device. The work is held in a clamp which carries it beneath the flame. The clamp is of such form as to divide the enveloping flame into two streamers, one lying along the seam ahead and one lying along the seam to the rear. Naturally, with the work fixed as in a ship's hull, it would be necessary to move the torch. The workman may do this or it may be done with a device adapted for shifting along the seam. This arrangement is calculated to quicken the welding operation, thus saving the time of the workman and reducing the expense for oxygen and acetylene. It is to be distinctly noted, however, that it does not provide for the restoration of the grain size of the steel.

To deal with the grain size, there must be an interruption. After the welding operation, the weld and adjacent work must cool, at least to, say, black heat before the re-heating begins. Consequently, the enveloping flame could not always be used simultaneously with the working flame, the latter doing the welding and the former doing the restorative work. There are, however, less expensive flames to use for re-heating—city gas or natural gas. That they shall act with great power is not so necessary as that they will not project products of combustion of a harmful character on to the metal. This point covered, almost any form of fuel will do that is reasonably manageable and capable of producing enough heat to bring the seam and adjacent regions up to temperatures ranging from full cherry red to, say, orange.

Objection to Refined Iron

It has been customary among oxy-acetylene welders working on steel to use some pure form of iron for the new metal to be put into the groove—Norwegian and Swedish iron and one or two American brands of refined iron. The idea seems to have been to prevent burning by supplying little or no carbon. The new metal is ordinarily in the form of a rod. Naturally, in moving this rod about it is liable to be exposed to the air. If it contained much carbon, the ordinary workman would probably be burning the hot end continually. Besides, the use of refined iron is at best only a partial remedy against carbonization, since the adjacent work may still be affected. Furthermore, it does not deal at all with the condition resulting from big grains.

A second objection to the use of refined iron for the restoration of the quality of the steel when re-heating concerns the matter of the normal strength of the material prior to any deterioration from any source. It is well known that iron is by no means as strong as steel. Only a comparatively few people know, however, that the tensile strength of steel is strictly proportional to its carbon content. This rule covers at least all steels below tool steels. Each small addition to the carbon percentage means a considerable addition to the strength.

H. H. Campbell gives, in effect, the following rule: Beginning with steel of a zero carbon content—40,000 pounds per square inch of cross-section is assumed as the ultimate tensile strength of basic or open-hearth metal— for each 0.01 per cent. added to the carbon content, 1,000 pounds is to be added to the initial valuation of the strength at 40,000 pounds.

It may be gathered from the foregoing that pure iron is hardly in the same class with steel. A weld made of pure iron will probably consist of material weaker than the adjacent steel plates, if the latter are of first quality, even if no deterioration of the iron occurred in the welding process.

Another Objection and Summary

I have also further objections to make to this custom. From information about iron and steel which has been developed during recent years, it is understood that the re-heating process is quite successful with steels containing between 0.50 and 0.90 per cent. of carbon, but less so with steels containing smaller percentages.

To sum up, the oxy-acetylene process can probably be employed with success in marine work, not only in connection with ordinary miscellaneous jobs, but with work of welding the joints in the hulls of steel ships. But—and note this "but"—if only the ordinary procedures are employed, the tensile strength of the material at and near the weld is to be reckoned as decidedly less than that of the plates. Restorative measures are possible, but they must be applied intelligently and adequately.

Halifax.—The use of the Public Market Building for a mold loft has been requested by the Halifax Shipyards, Ltd. The intention was to lay the first keel early next month, and they had been unable to find a suitable building, except the market. The letter has been referred to the City Engineer.

WELDING IN RAILWAY SERVICE

Economies Realized

The Sayre shops of the Lehigh Valley Railroad claim the distinction of having turned out, about five years ago, the first completed welded firebox placed in service on an American railroad, and the plant is still turning to good account the economies possible through the use of oxy-acetylene and electric welding.

So far have improved methods of doing boiler work progressed at this plant that locomotive fireboxes are regularly renewed without removing the boiler from the frame, it being the practice to cut out the original firebox and put in in three sections, welding up all seams and joints. Among other expedients employed is that of dispensing with the studies at the corners of the mud rings, the practice being instead to countersink holes through the firebox sheets and into the mud rings sufficiently to get clean metal, and then spot weld the sheet to the mud ring by filling up the holes with the welding torch.

It has also become the regular practice to reclaim car and tender axles having worn collars by the oxy-actylene torch. The collar is built up the required amount, and then machined to the standard contour. In case the material deposited is found to be too hard, resort is had to the process of annealing the ends of the axles to enable the lathe tool to take hold. The expense involved in this process is given as $2.34, as compared with $20, the approximate cost of new axles for 50-ton cars. In cases where the rocker or tumbling shafts of locomotive valve gear mechanisms have become worn these parts are built up to size and restored to service at a fraction of the expense involved in renewing them. Loose fits on the crankpins and driving axles of locomotives are similarly treated. Locomotive driving box shoes are attached in the same manner as are the firebox sheets at the corners of mud rings—that is, by spot welding.

Cracked sylinders, which to replace new would cost anywhere from $800 to $1,200, are restored to service by autogenous welding at a cost that is insignificant in comparison. Broken engine frames are regularly welded in place, and miscellaneous lugs and brackets, including those on air pumps, are also restored by this means. A further economy to be observed at the Sayre shops and one in which the oxy-acetylene torch plays its part is the cutting out of blanks from old boiler shells from which locomotive driving brake heads are pressed in the bulldozer. The expense of making these heads amounts to about 35c each, as compared with more than $2, the present cost of these parts if made from malleable iron or steel castings. So fully is the value of autogenous welding appreciated by the mechanical staff of the Lehigh Valley Railroad that part of the standard equipment at each of its modernized engine terminals consists of an electric welding equipment The types of machines which represent with its automatic control panels.

Ways to Shorten Arithmetical Calculations

Many Short Cuts Are Possible in Mathematical Calculations—Result in a Considerable Saving of Time—Checking of Multiplication Ensures Accuracy

By DONALD A. HAMPSON, Assoc. Mem. A.S.M.E.

In most shops and offices there is some one man who is known to be "quick at figures." It will be found as a rule, that that man practises various short methods of arithmetic and does many of his calculations mentally, also that he keeps up his speed by constant applications of these, even though no time is saved in some instances. To be able to calculate while on the feet is a valuable attainment; of course, extended calculations are impossible, but often these may be reduced so that they are possible, if a person memorizes a few rules and keeps in practice by being always on the lookout for chances; mental arithmetic used to be taught in the schools (and perhaps is yet) and many of the executives of to-day owe their start to the fact that they acquired a reputation above their fellows from that training. Some of the short methods are great time savers on everyday work, though not all can be performed mentally. About the only way in which these appear to shop men is when a contributor offers a single application in one of the trade papers; the reader passes this by with a mental note for the future, but when he wants it most, he cannot find it. The following are offered in the hope that collectively they will be retained and studied, memorized and put into practice. Some readers are familiar with them all, others will say, "I learned that in school, but forgot it years ago," and to others they will be entirely new.

Cancellation

Handling small numbers is so much easier than large ones and the chances for errors are so much less that every calculation should have its units reduced to smaller ones, if possible, at the very beginning. The everyday formulas and equations of applied mechanics form conspicuous examples—horsepower and weight and speed calculations are typical. Assume that the diameter of the driving pulley to put on the main shaft is wanted, and the other pulley sizes and the speeds are all set down as follows in the well-known formula:

$$D = \frac{1600 \times 8 \times 6}{150 \times 16} = \frac{76800}{2400} = 32$$

$$D = \frac{\overset{32}{\cancel{1600}} \times \cancel{8} \times \overset{3}{\cancel{6}}}{\underset{5}{\cancel{150}} \times \underset{4}{\cancel{16}}} = 32$$

If done by multiplying out, the result is as shown first and involves putting down all the figures; if done by cancellation, as shown second, the result is obtained almost by inspection and in far less time.

Fractions are one of the commonest mediums of calculations, and one of the simplest, but many men (and youths just out of school) are scared at their mention. They appear less formidable if kept reduced to their lowest terms. Whole numbers multiplied by fractions are frequent causes for mistakes when the whole number is first multiplied by the numerator, and then the division performed; while if the number is divided first by the denominator of the fraction and then the quotient multiplied by the numerator, the terms handled are smaller, with consequent less chance for mistakes. Thus 7-8 of 24392 is more easily done.

$$\begin{array}{r} 8\,\underline{|24392} \\ 3049 \\ \underline{7} \\ 21343 \end{array} \quad \text{than} \quad \begin{array}{r} 24392 \\ \underline{7} \\ 8\,\underline{|170744} \\ 21343 \end{array}$$

Division of Fractions By 2

Division of fractions and mixed numbers by 2 is a daily task, no matter how complete blue prints and instructions may be. When a fraction such as 18-32 appears—a fraction with an even numerator—one mentally reduces it to the simpler form of 9-16 on inspection. But if the fraction to be divided by 2 is, say, 19-32, we often find a person going at it as

$$\frac{19}{32} \div 2 = \frac{19 \div 2}{32} = \frac{9\frac{1}{2}}{32}$$

and then going through a process of reducing that to the result, 19-64, instead of following the rule for such cases of leaving the numerator unchanged and doubling the denominator. Then half of 19-32 becomes

$$\frac{19}{32 \times 2} = \frac{19}{64} \text{ and } \frac{17}{57} \div 2 = \frac{17}{57 \times 2} = \frac{17}{114}$$

If a number like 10 13-32 is divided by 2, the whole number is divided mentally and the fraction likewise, following the rule just laid down, the result being 5 13-64.

Mixed Numbers Divided By 2

But if the whole number of a mixed number happens to be odd, the division is not so easily accomplished unless the following rule is applied. For the integer, divide the next lower even number by 2; for the fraction, the denominator is twice the original denominator and the numerator is the sum of the original numerator and denominator. Several examples will illustrate this,

Divide $5\frac{17}{32}$ by 2
Next lower number is 4
$4 \div 2 = 2$ (1)
$2 \times 32 = 64$ (2)
$17 + 32 = 49$ (3)
And the quotient becomes $2\frac{49}{64}$

$1\frac{11}{16} \div 2$
Denominator $= 2 \times 16 = 32$
Numerator $= 11 + 16 = 27$
Quotient $= \frac{27}{32}$

$395\frac{7}{8} \div 2$
Half of $394 = 197$
Half of $1\frac{7}{8} = \frac{15}{16}$
Therefore $395\frac{7}{8} = 197\frac{15}{16}$

which is one of the handiest short cuts.

Simplifying Fractions

Fractions often are more accurate and faster than would be the solution if they were changed into decimals. A practical application is afforded by the following, which was the result of substituting figures in a well-known formula

$$\frac{\frac{1}{2} \times 7854 \times 3\frac{1}{2} \times \frac{3}{8}}{9 \times \frac{7}{18} \times 4 \times 12}$$

where a first change is made by writing 7-2 in place of the mixed number. Then by the rule that when a fractional numerator or denominator is present, the denominator may be changed to the other side of the line of division if accompanied by the sign of multiplication, we write

$$\frac{\frac{1}{2} \times 7854 \times \frac{7}{2} \times \frac{3}{8}}{9 \times \frac{7}{18} \times 4 \times 12}$$

which equals

$$\frac{1 \times 7854 \times 7 \times 3 \times 18}{9 \times 7 \times 4 \times 12 \times 2 \times 2 \times 8}$$

and proceed to cancel for a quick and easy solution. By the same rule other fractions are rendered "harmless," as

$$\frac{\frac{7}{8}}{10} = \frac{7}{10 \times 8} = \frac{7}{80} \qquad \frac{10}{\frac{7}{8}} = \frac{10 \times 8}{7} = \frac{80}{7} = 11\frac{3}{7}$$

Dividing By 12½

We often encounter the number 12½ in dividing 25 or 50, and almost as often have to continue the problem with 12½ as the divisor. An easier way than setting down the numbers and performing the division is to multiply the number by 8 and point off two decimal places to the left. Thus 24550÷12½ = 1964, but that cannot be done mentally, whereas 24550x8 = 196400, and pointing off becomes 1964. This can be done mentally or by writing the result without setting down the factors. If desired, the pointing off may be done first—then 245.50x8 = 1964.

Squaring Numbers Ending in ½

A number ending in ½ as 6½ may be squared mentally. Instead of performing the multiplication on paper it is done in the head simply—7x6 plus ¼ is 42¼. The rule is, multiply the number by one more than itself and add one-quarter. To illustrate with a larger number, square 19½—(one more than 19 is 20) then 20x19+¼ is 380¼, or 380.25 if we choose to use decimals.

Squaring Numbers Ending In 5

Squaring a whole number ending in 5 is done by a somewhat similar process: First, drop the 5; then multiply the remaining number by one more than itself; to this product affix 25 and the result is the desired square. Example: square 325. Dropping 5 leaves 32 and one more than 32 is 33; then 33 × 32 = 1056; 25 affixed (not added) to 1056 = 105625. It is a relatively short task to square this number by the usual long multiplication, but if the method given above is fixed in the mind ready for instant use, some time is saved by its use and when the number has four figures or more (as 4525) less computation is necessary. Numbers of two figures may be squared mentally—65² would be x 7 with 25 affixed, becoming 4225 almost at a glance.

Checking and Proving Multiplication

In checking over a multiplication they have made, many persons will commit the same error (mentally) that they did when setting down the figures, a thing that has been done so often that an entirely different proof is far better. The proof that follows is one of the best and quickest. Add the individual figures of the multiplicand and if the sum is greater than 9 add these figures to get a sum of only one figure; do the same thing with the multiplier; multiply these sums and the product will equal the sum obtained by adding the figures of the product of the original multiplication until a sum of one figure is reached. This is easier than it sounds, as witness below—

```
  6293     6+2+9+3 = 20    2+0 = 2    2x3 = 6
   372       3+7+2 = 12    1+2 = 3
 -----
 12586
44051
18879
-------
2340996    2+3+4+0+9+9+6 = 33    3+3 = 6
```

Contracted Multiplication

Very often a multiplication involves more decimals than are needed for accuracy. Innumerable calculations would be amply correct if the result were stated to one or two or three decimal places. A method known as short or contracted multiplication cuts out a good deal of work and gives a result to as many decimal places as wished. The example following shows how the work is set down and performed. Required to multiply 12.472 by 1.234.

```
 12.472
  1.234
 ------
 12.472  = 1 x 12.472
  2.494  = 2 x 12.47
   .372  = 3 x 12.4
   .048  = 4 x 12
 ------
 15.386
```

Though in this case both numbers have the same number of decimal places, it is simpler in any case to place the decimal points under one another (if one of the numbers had had more than three decimal places, those over three would have been disregarded). Proceeding with the multiplication it will be noted that instead of following the usual order and multiplying with the 4 first, the start is made at the other end with the 1 and the result, 12472, set down, keeping decimal points in a vertical line. After this multiplication the last figure in the multiplicand (2) is crossed off and disregarded henceforth. Then 12.47 is multiplied by 2. the product set down in line. and another figure (7) crossed off. This is continued and the sum is the final product, 15.386, to three decimal places. To give a clearer idea of the order in which the multiplying is done and what figures are crossed off, another row of figures had been placed at the right showing how each individual product was obtained. If the multiplication had been performed in the usual long way, the result would have been 15.390448, which is .004 greater than the abbreviated method and sufficiently close for many purposes.

A way of squaring numbers of two or more figures will be given. For an example we will take the number 78 and square it. The rule is: Subtract the number from the next higher tens number, subtract the difference thus obtained from the original number, and multiply this new difference by the tens number, and to the product add the square of the difference first found. This seems very involved, but it isn't, as may be seen below and the process can usually be worked out mentally. In the case of 78, 80 is the next higher tens number: if the number were, say, 124, the tens number would be 130 and the procedure would be the same.

```
80 — the next higher tens        78
78 — the number                   2
--                               --
 2 — the difference              76
1st subtraction                  2nd. subt.

76 x 80 = 6080     2 x 2 = 4          6080
                   squaring the          4
                   difference         ----
                                      6084
multiplication                        the answer.
```

Time Savers for Weight

Along with the strictly mathematical short cuts above there are a couple of others that will help the man who has to do with weights and volumes of metals.

In case the weight or volume of a round bar is wanted, use ¾ of the square of the diameter instead of .7854. This enables many estimates to be made mentally and is near enough when the weight is not over two figures and the material steel ir iron.

It is not hard to remember that ½" steel weights 2-3 of a lb. to the foot, ⅝" weighs 1 lb., ¾" weighs 1½ lbs., 1" weighs 2 2-3 lbs., 1½" weighs 6 lbs., 2" weighs 11 lbs.

A rule to find the weight per foot of length of any round steel bar is: square the number of quarter inches in the diameter and divide this by 6, the result is the number of pounds.

For rough estimating the weight of cast iron, wrought iron and steel may be taken as ¼ lb. to the cubic inch, or four cu. in. to the lb. Bronze and copper are heavier—approximately three cu. in. to the lb. or 1-3 of a lb. to the cu. in.

DEVELOPMENTS IN SHOP EQUIPMENT

Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

LITTLE DAVID PNEUMATIC CAULKING MACHINE

With the demand for ships and more ships to make good the losses caused by U-boats, and with the shortage of skilled labor, due to the war, a tremendous need arose for mechanical tools to increase and speed up the building of ships, which was a pretty slow process in the days when all the work was all done by hand.

CAULKING MACHINE

To-day, a large percentage of the work is done by machines—the power used being compressed air. The following will give some idea of the various uses: riveting, chipping, drilling wood and steel plates, caulking steel, caulking oakum, grinding, sawing, driving drift bolts, and trenails on wooden boats, blowing cement, blacksmith forges, bolt heading machines, planing and dubbing machines, painting and operating small hoists.

The tacking of oakum by mechanical means on the hulls and decks of wooden ships and on wooden decks of steel ships, was never a success until an inventor on the Pacific Coast designed the Little David Pneumatic Caulking Machine, which meets the peculiar requirements necessary, such as coiling or tacking cotton or oakum (either machine or hand spun), to any required depth for final horsing.

The machine is easily handled, weighing only 13¼ lbs. The length over all is 22 inches, and the air consumption at 90 lbs. is 20 cu. ft. of free air per minute. In appearance the Little David pneumatic caulker is similar to a pneumatic riveter, but its action is totally different, being on the same principle as the sand rammer or sewing machine. Guide wheels are used to keep the machine in line with the seam. The stroke being always the same, the depth to which oakum is forced in the seam is regulated by the operator's pressure on the tool.

The caulking machine operates at the rate of 1,500 tacks per minute, either coiling the oakum or running it straight.

A metal finger at one side over which the oakum passes before it is forced into the seam by the iron, regulates the coiling or tacking. For a long tack the iron is allowed to pass further; for a short tack the normal stroke or position is used.

In standard tack work, such as 5 in. or 6 in. planking, the method employed in certain U. S. yards is to run in the first three strands almost straight to allow cotton or oakum to penetrate farther. The first horsing is then given. The seam is now filled up with two more strands, having these well pinched or coiled, and again horsed. Care must be taken to see that there are no lean places or lumps in the material, otherwise skipping or uneven caulking will result.

All seams on 5 in. or 6 in. planks should be reamed to a depth of 2¼ in. and about 3-16 in. to ¼ in. open at the top.

For the deck with 3 in. planking, ream about 2¼ in. deep, and from ⅛ in. to 3-16 in. open at the top.

Caulking decks, until recently, has always been a slow and tiresome job, but the Little David Caulking Hammer seems to have changed this, as the following test at the Vancouver yard of the G. N. Standifer Corp. proves: 3,100 ft. of single thread oakum was driven home, and time test showed 35 ft. of one seam was completed in 3½ minutes. At the Fraser, Brace and Company's yard, Montreal, where they were using a number of these caulking machines, the following results were obtained in the course of their ordinary work, and without any special test: 41 deck seams, 21 ft. long, were completely finished—that is, both tacked and horsed—in 2½ hours.

In this case two men and two machines were employed, one machine fitted with a 1-16 in. iron for tacking, and the other with a 1-8 in. grooved iron for horsing.

In tacking, the first operation an iron 1-16 in. thick is used. For the horsing of the decks an iron 1-6 inch thick is used, or in some cases we have noted a 3-16 in. iron with a groove, which seemed a decided improvement. A few seconds is all that is necessary to change from one iron to the other.

As stated previously, this No. 23 Little David caulking machine will tack oakum in any part of the hull or deck, but will only do horsing on the deck. The inventor is now endeavoring to design a suitable horsing machine.

It has been estimated that this Little David caulking machine will take the place of ten mechanics. A man by hand will take an average of three days to caulk in a bale of oakum; with a machine the bale will be caulked in an average time of 2½ hours.

CAULKING DECK PLANKING

This new tool seems to have filled a big vacancy, and from all appearances is here to stay. Wooden ships may not be built very much longer, but the building of steel boats with wooden decks, which require caulking, will be one of Canada's large industries in the future.

IMPORTANCE OF THE LABORATORY IN THE MODERN FOUNDRY

THE importance of scientific guidance in industrial pursuits has been very forcibly brought to the attention of almost every manufacturer in the past few years. Many industries have been compelled to pay the very strictest attention to the composition and physical properties of the materials entering into munitions of war.

The foundry has not escaped this general inquiry into ways and means of bettering plant processes, and while the semi-steel shell so far as America is concerned was only coming into its own the advice of French authorities may well be applied to foundry work in general.

General Camon and Lieut. Rouger in their investigation into the semi-steel as a material for shells made some very pertinent observations regarding the industrial laboratory. They found in an exhaustive inspection of foundries made in the latter part of 1915 and the first part of 1916 that a great variance was observed in the results obtained by the French founders. While some of them had a number of rejections of only 10 or 15 per cent. other foundries exceeded 50% rejections on the 155 mm. shell. These show that for the latter there were systematic errors in the latter places which should be investigated and eliminated.

For this reason it was advisable to sum up in a concise note the general principles which are at the basis of the development of semi-steel and to draw attention to the most important of these points. Since then the establishments had encountered new difficulties because the iron and cokes were no longer of as good a quality as those which had been used at first. Means had to be found to remedy this condition and different plants were communicated with as to the result of their studies in this connection. Some well known foundries had thought they could handle semi-steel as they had handled ordinary cast iron, by pure experiment. They had the troubles which they deserved, having been compelled either to abandon manufacture of semi-steel shells or to adopt, like their colleagues, methods based upon chemical analysis.

Obviously one could not fail to recognize the value of experience acquired in the course of long practice, but this experience must be associated with logical investigation.

Lacking laboratory analysis some manufacturers assumed that for each kind of piece to be cast the fusion bed or cupola mix, would be composed of definite proportions of iron marked as to its source and the appearance of the manufacture. Consequences resulting from this procedure were made apparent in—

First, the foundryman was at the mercy of certain producers; the lack of iron of a certain origin became the cause of embarrassment in the manufacture.

Second, the constituents of an iron of definite origin are always essentially variable, for they depend not only upon the ore but upon methods of manufacture. Even assuming an ore always of the same grade any mistake or accident in the operation of the blast furnace has its effect upon the chemical composition. These variations cannot be recorded with sufficient accuracy without the aid of the chemical laboratory.

Third, when a series of pieces is defective in quality of material it is more difficult without a laboratory to investigate and to remedy the cause.

Fourth, when the composition of the iron which should be obtained is definitely known fusion beds may be arranged, with the help of the laboratory, with materials at hand by varying their proportions.

By its very presence in the foundry the laboratory exerts a good effect upon the quality of the metal received; thus a Berlin foundry found after it had established a laboratory that a notable improvement resulted in the metal received, particularly as regards the sulphur content, the purveyors to avoid exposing themselves to a refusal on the part of the laboratory selected their product themselves and kept back sulphurous metal for the foundries which could not make analyses on reception.

To-day foundries working with semi-steel which do not have a laboratory and are satisfied with analyses made outside are exceptional in France.

FUTURE AND SOURCES OF INDUSTRIAL ALCOHOL

Possible Sources of Supply

THE appointment of a Government Committee to investigate the available sources of supply of alcohol, with particular reference to its manufacture from materials other than those which can be used for food purposes, the method and cost of such manufacture, and the manner in which alcohol should be used for power purposes, has served to focus attention upon a problem of the most vital importance for England's post-war period.

For the purposes of war it was found possible to meet the needs of the explosives industry for both alcohol and acetone by a drastic reduction in the quantities of potable spirit bonded, by augmenting the capacities of the distilleries producing spirit, by importation of over-proof spirit from various parts of the Empire, and by increasing distillation from molasses. The alcohol thus obtained has been deprived practically entirely from materials otherwise available as food, and, indeed, in the case of molasses has been secured at the serious expense of the supplies ordinarily employed for stock-feeding. In the year 1916-17 the consumption of industrial spirit had reached a figure of upwards of four million gallons. With the close of hostilities a large part of this demand for alcohol in industrial processes will not be maintained. Nevertheless, it is confidently anticipated that the output of alcohol will not suffer any diminution, but, on the contrary, will be increased to many times its present magnitude.

Fuel Uses

The outlet for the alcohol of the future may be deduced from the terms of reference of the Government Committee, and also from the composition of the Committee appointed. The presence upon the Committee of Inquiry of a number of technical experts interested in petroleum supplies and their application demonstrates that the problem of alcohol is intimately connected with the development of motive power, in which a high-grade volatile fuel is consumed. The enormous increase in the applications of the internal combustion engine for transport on land, on sea, and in the air has placed a strain upon the producers of petrol supplies which shows no tendency to diminish. The oil supplies of the world, drawn upon to an ever-increasing extent, are rapidly becoming inadequate to meet the demands which arise. Thus, it will be necessary to turn more and more to other sources of fuel supply. Among these, not the least of future possibilities is presented by industrial alcohol, suitably denatured, in admixture with benzine, the production of which in large quantities from by-product ovens and town's gas is practically assured.

Grain and Potatoes

In this country, at present, alcohol is mainly obtained by fermentation processes from grain, together with some small quantities by distillation of molasses. In Germany production from potatoes by a combined hydrolytic and fermentation process has been largely used to supplement the grain fermentation process. The first stage in the operation consists of the conversion, by treatment with acids, of the starch content of the potato into glucose, a soluble sugar, which is then fermented to yield the alcohol desired. The raw materials for the preparation of starch, such as rice, maize, and sago, are also suitable for use in the production of alcohol by this process. In the main, however, the starch content of such materials is used as such, or is converted into glucose only, to be used in the many sweetening processes for which this product is suitable. In all of these alternatives, however, potential food supplies are consumed, and during periods of stringency, such as now hold, economy of such supplies is a problem of the utmost urgency.

Of the possible sources of alcohol supply other than those which have just been enumerated, attention has been directed to the utilization of wood waste, and to the synthetic production of alcohol from calcium carbide, a product which can be produced abundantly and cheaply in the electric furnace, provided that cheap electric power is available.

Utilization of Wood Waste

The principal constituent of wood is the complex carbohydrate commonly known as cellulose, and this is available in abundant quantities in the wood waste obtained in the operations of the timber trade. The problem of recovering alcohol from such material consists in the conversion by disintegration of the cellulose constituent of the wood into fermentable sugars, from which alcohol can then readily be obtained. The possibility of effecting such a conversion has been known for more than a century, and many attempts at commercial realization of the project have been made. It is only recently, however, that success has become practicable, largely owing to detailed study of the problem by the lumber interests in North America, stimulated by the assistance of Government investigation, such, for example, as that conducted by the U. S. Forest Products Laboratory at Madison, Wisconsin, U.S.A.

To convert the cellulose of wood waste into sugars suitable for alcohol fermentation, treatment with dilute acids is employed. Dilute sulphuric and hydrochloric acid and, more recently, sulphurous acid have all been tried. In the modern developments of the process the wood waste is saturated with water containing 1 per cent. of acid, and the mixture is digested at suitably elevated temperatures, corresponding approximately to a pressure of 75 lb. to 100 lb. of steam, for a definite interval of time. The moisture content is kept as low as possible for the sake of economy in the subsequent neutralization and concentration processes as well as for greater ease of handling the material and regulation of the operating conditions. It has been found that a 50 : 50 wood-acid liquor is a convenient material for such purposes.

After the process of digestion the separation of the sugars from the woody residue is effected in standard beet-sugar diffusion batteries provided with acid-proof linings. Neutralization of the acid liquors follows, generally by means of lime or a high-grade limestone. The sugars are then fermented in accordance with standard practice, a four-day fermentation period being employed, and the alcohol is subsequently distilled and rectified in the usual way.

Comparative Yields

As to yields, obtained and possible, it may be observed that 25 to 28 per cent. of the dry wood may be rendered soluble, and of that percentage as much as 80 per cent. is fermentable sugar. This corresponds to 10-11 per cent. alcohol, or 35 gallons of 95 per cent. spirit per dry ton of wood. Thus far, in actual practice, the yields have scarcely exceeded 20 gallons per ton, as contrasted with a yield of 80 gallons per ton from corn. It is obvious, therefore, that the amount of material handled in parts of the plant producing alcohol from wood will be four times as great as in a grain distillery with equal output. On the other hand, there is a large margin in the cost of raw material in favor of alcohol from wool waste, and the fuel charges are always a much smaller item than in a grain distillery, since most sawmills produce waste in excess of their own power requirements, and the woody residues from the digestion process have a fuel value after partial dehydration. With modern plant the economic aspect of the problem becomes steadily more favorable, and the wood waste alcohol industry may leap forward to commercial success as the shortage of other available fuels for internal combustion engines becomes more acute. Such developments, which have so far been confined mainly to the United States, may be expected to occur also in Canada and other timber-producing areas.

A development of the alcohol industry from wood as raw material, which has been greatly stimulated in Sweden and in Germany during recent years owing to the rigorous curtailment of imports of petroleum spirits, is associated with the paper-making industry. Wood pulp is produced from pine-wood material in considerable quantity by digestion of the wood with solutions of sulphite of soda. The sulphite lyes contain fermentable sugars, and are therefore potential sources of alcohol. Apparently the difficulties associated with the dilution and composition of the liquors have been successfully overcome, since 11 factories are now in course of erection in Sweden, a development which suggests that Scandinavia will soon be independent of petrol supplies.

Synthetic Processes

To a country such as Britain, with no considerable timber areas, the synthetic processes of alcohol manufacture must be of prime consideration. As developed hitherto calcium carbide is the starting point of the synthesis, a fact which suggests the necessity of cheap power production, as outlined in recent Departmental reports. By treatment of the carbide with water, acetylene gas is obtained, and this on reaction with water in presence of a catalytic material is converted into acetaldehyde. From this latter, by a further process of catalytic reduction, alcohol results. The conversion of acetylene to alcohol thus involves two separate catalytic processes. The first, the process of hydration with water, is carried out in presence of suitable acids, generally with mercuric oxide or mercury salts present to promote the rapidity of the process. Sulphuric acid and acetic acids with the corresponding salts of mercury have been employed, and, as they are unchanged in the reaction they can be utilized for long periods of time. The aldehyde produced is subsequently passed in the form of vapor, together with hydrogen, over a catalytic material consisting mainly of reduced nickel. At 140° C. 80 per cent. of the aldehyde may be converted into alcohol by one passage over the nickel, and the residual hydrogen and acetaldehyde may be returned to the catalyst, after being freed by fractionation from the alcohol formed. In this way high efficiencies may be obtained.

It has been recently stated that, operating in this manner, successful production has now for some time been carried out by the Hoechst Farbwerken in Germany and by a Swiss company, the Longa Electricity Works, at Visp, Switzerland. It is hoped that this latter company will shortly be in a position to cover the total alcohol consumption of their country with the synthetic product. The economy of the process is conditioned mainly by the initial cost of carbide, which must necessarily be extremely low to furnish alcohol at a price which would compete successfully with petrol at normal rates. Large-scale production in favorable conditions as to power costs will certainly be necessary.

The production of alcohol via acetaldehyde does not exhaust the possibilities of synthetic processes. Large-scale production of ethylene hydro-carbons would lead to the development of a synthesis by direct hydration, from which alcohol would result in a one-stage operation. The whole problem is as yet in its infancy, and a considerable amount of coordinated research will be necessary to establish the alcohol industry on a sound basis. The need for alcohol as fuel becomes increasingly urgent, especially in areas such as the United Kingdom, in which natural resources of motor fuel are but small. The restrictions under which the manufacture of industrial alcohol has labored in the past will disappear inevitably as the need for alcohol grows. The growth of the industry will follow the present stimulation of investigation and research.—

CASTING IN ALUMINUM

By M. M.

The use of aluminum for castings which are not subject to great direct pressure is likely to increase, because of its lightness and its freedom from oxidization at atmospheric temperatures. It is of great value in aeroplane and submarine work especially, but it is not much used in a pure state. Where lightness and not strength is the chief consideration, alloys that have a very high percentage of aluminum are used, probably only about 1 to 7 per cent. of copper being added; but if toughness is essential and great tensile strength, aluminum bronze composed of 90 per cent. of copper and 10 per cent. of aluminum is good. This mixture is satisfactory for sea valves and small propellers, as it withstands the corroding influence of the sea water. What is called aluminum brass is really just an addition to a small percentage of aluminum to a copper and zinc mixture. It makes a tough alloy suitable for forging, but the percentage of aluminum is so small, probably 3 or 4 per cent., that it makes no appreciable difference to the weight of the casting. One great advantage of this mixture is that if a slight alteration is wanted in a casting the metal will draw out. For small bed plates, gear cases, and brackets, a very suitable alloy is 85 parts of aluminum to 11 parts of zinc and 4 parts of copper. It is true of all casting, but perhaps more especially of aluminum, that a great deal is found by trial, consequently mixtures are varied slightly to suit special classes of work.

Aluminum is a difficult metal to melt. It oxidizes readily, and the furnace temperatures should consequently be low. A gas or oil furnace is much better than the ordinary crucible fire. When it attains a dull red heat it should be poured. A flux is not necessary if care is exercised, but some common salt or zinc chloride may be used, the metal afterwards being stirred and skimmed. In mixing aluminum alloys for small work the copper should be melted first, and when it is fluid the aluminum may be added and stirred up with an iron rod. It is better, however, to add it as half aluminum, half copper, because the melting temperature of copper being so much higher—over 800 deg.—than aluminum, there is a danger of overheating. In making this mixing alloy the copper should be melted first and the aluminum added in small quantities. The alloy is heated first. and then the aluminum is added. Of course, if a zinc mixture is used, the zinc as usual is added last.

Much of the success in aluminum casting depends upon pouring the metal at the correct temperature. This can be determined by skimming the metal as it is melting. When it is right for pouring there will be no oxidization, and the surface will be clear. There is much disputing as to the effect of re-melting aluminum alloy, and the results of experiments seem to show that a mixture which is rich in aluminum is generally improved by re-melting, but when the percentage of aluminum is small, its strength is reduced.

Care has to be taken when making molds for aluminum work that the ramming is not as hard as for ordinary gun-metal or brass castings. The shrinkage of aluminum is considerable, and if the sand is hard rammed, it will interfere with the free contraction of the metal, and distorted or cracked castings will be the result, otherwise there is not much difference then from ordinary brass founding. A good facing sand mixture is composed of one part of Mansfield sand to three parts of floor sand. For thin metal however, more floor sand should be used. It should be put through a fine riddle. French chalk or plumbago may be brushed over the mold. but occasionally a facing powder is dispensed with.

The cores for such molds should be well vented, as the metal is too light to force the gases out. An open sand is best, and sea sand is sometimes used with a strong binder.

Because of the shrinkage in such work, larger feeder heads are indispensable, especially if the metal is thick. As soon as the metal sets the casting should be stripped, and to facilitate this, some molders prefer wooden flasks, which are light, and thus easily handled. Apart from this advantage, however, although wooden flasks are very handy, as they can be quickly made, cast iron boxes are preferred by most molders.

ESTIMATING PHOSPHORUS IN BRONZES

By M. A.

Bronze drillings, to the amount of from 0.5 grm. to 2 grm., are dissolved in a mixture of 20 c.c. strong nitric acid and 10 c.c. strong hydrochloric acid, or, if preferred, 60 c.c. nitric acid (specific gravity, 1.135), and 10 c.c. hydrochloric acid. The mixture is digested for some time without boiling, until most of the red fumes have been evolved. If the concentrated acids are used, the mixture is then diluted to about 70 c.c. The liquid is next cooled and 40 c.c. of ammonia (specific gravity, 0.96) added slowly, with constant shaking, followed by 35 c.c. of niromolybdate solution, and the whole shaken well for a few minutes. The mixture is allowed to stand for one or two hours until the precipitate has settled out, when it is filtered, preferably on pulp, washed with water until free from acid, the filter and precipitate transferred back into the flask, excess of N-20 caustic soda run in from a burette, the whole well mixed and the excess of caustic soda titrated with N-20 sulphuric acid, using phenolphlathein as an indicator.

1. c.c. N-20 caustic soda = 0.00337% P. on 2 grm.

The method is based on the well-known volumetric method of estimating phosphorus in steel. It is best carried out in a 600 c.c. conical flask and a rubber stopper used in the final shaking.

Points

1. The digestion with acid must be long, to oxidize all the phosphorus, or results will be low.

2. Boiling or heating must not be too prolonged, or tin will be precipitated and will be difficult to redissolve.

A comparison of the method has been made with a gavimetric method, in which the tin oxide containing the phosphorus is mixed with Hepar mixture and fused. The resulting melt is dissolved in hot water, the solution acidified with a little hydrochloric acid, whereby the tin is precipitated.

The tin sulphide is allowed to settle, and is then filtered off, the filtrate being boiled to remove sulphuretted hydrogen; nitric acid is added and taken down to low bulk, and the phosphorus precipitated and estimated as magnesium pyrophosphate in the usual way.

The results obtained by the two methods on a number of commercial bronzes are given in the accompanying table along with the approximate composition of the bronzes.

					Phosphorus	
Copper	Tin	Lead	Zinc	Iron	Gravimetric	Volumetric
88.32	2.56	8.08	0.11	0.24	0.45	0.42

THE FUTURE OF IRON

In the course of his presidential address to the Staffordshire Iron and Steel Institute, Mr. G. Carrington prophesied that the demand for iron in the future will greatly exceed that of the past. Its greater suitability for sheets, whether black, painted, or galvanized, is generally conceded, its life being fully five times that of steel, and even in present conditions it is again ousting steel for railway and colliery work, ships' decks and hatches, and where there is exposure to severe weather or to acidic liquids. Then there are plates, girders and bars for bridge building and constructional and agricultural purposes, and particularly for ships; and he expressed the conviction that, given the material at a reasonable price (not the same price as steel, because it will always command a better price for these purposes than steel), we shall in our time see the all-iron ship. But it is necessary to devise methods by which the necessary output can be obtained, and in his opinion there is no way except by large gas-fired mechanical puddling and scrap furnaces of anything up to say. five tons, with corresponding mill and other necessary plant. There will then be no difficulty in producing ships' plates and girders in the large sizes now required, without which an iron ship could not be economically built. The rudder and stern may give trouble, and steel will perhaps be specified on account of the thickness, weight, and shape required, and also the relative unimportance of rusting, but for plates, girders, bars, etc., for bridge building and constructional work there would be no difficulty. A Puddling Research Committee has been formed by the whole of the iron trade associations of the country, and it is to be hoped that something may be done to relieve the puddler of some of his heavy work. At present it is proposed to confine the investigations to 10 cwt. furnaces, but while that proposal represents a great advance. Mr. Carrington thinks it is much too timid. Producers must learn to talk in tons where they now think in hundredweights, and iron can be produced as economically as steel only on the same scale.

Unemployment is Dangerous

THE labor situation is not improving in this district. The only thing that is being done is the unloading of some hundreds of munitions hands every day or so. By the end of the month the shell plants of the Dominion will be done for, and the thousands that have worked there will be looking for something else to do.

If they do not find it they will be out of work. It may not take much reasoning to see that, but it is a fact so plain that it may be overlooked. Unemployment with prices at the present peak is a dangerous proposition for Canada.

Masses of men have felt their strength in recent years as they have never done before. There is more social unrest abroad now than there has ever been in the history of the country. These facts are patent to any person who is out enough to get in touch with the situation, and is honest enough to face the facts as they exist.

A season of unemployment with food and clothing and fuel at top-notch prices is too dangerous a thing to tinker with in this country just now of all times.

If Ottawa is going to move definitely the move should be made soon, if it is going to take the form of co-operation with the Canadian manufacturer, for it is to this source of employment that the people will have to look for some months to come to avoid an army of unemployed.

This country has the money and it would be a good and a sane investment to spend some of it in keeping the industrial and labor situation well ironed out until the cost of living shows some signs of coming down within shooting distance again.

Germany is "Out of Bounds"

PACIFISTS may try as much as they wish to seek easy terms for Germany in the making of peace, but every day that passes adds new evidence to the hell that has been turned loose in the name of German junkerism.

The man who would go out and preach hatred for the German simply because we had been at war with the German would be a fool and a traitor, but the man who can read the accounts of honest men as they describe what they have seen, and not have his whole being boil with indignation, is devoid of the semblance of manhood.

The anti-German feeling is growing without any urging. The chances are that we have not felt the full force of the movement. Remember we have some hundreds of thousands of soldiers who have yet to come home. These have seen atrocity in its worst form. They have come into contact with those that have felt to the limit the heel of the Hun. They have had an experience that a thousand years could not efface. And as these men come home, they will tell their experience. They will touch circles that have not been moved, and they will start influences and feelings that have been lying dormant. It will all grow into a tremendous anti-German feeling.

Germany stands not simply as a defeated country, but as an outlaw in the courts of civilization and an exile from the halls of decency. The murderer cannot wash his hands of the blood of infants and mothers, nor can the assassin come back into the company of decent men.

It's wasted effort carrying on a campaign against Germany and German goods. Germany's butchers in the last four years have blasted Germany's chances of getting a hearing in the commercial world.

Be Decent to the Salesmen

THERE are some firms, officials of which make it a point to turn down salesmen as a matter of policy. They know what they want and they apparently are satisfied that they know the place where they can secure it to the very best advantage.

When a salesman comes he can send in his card, and receive the information that the manager is too busy to see him, although at the time he may be trying to determine the difference between tweedle dee and tweedle dum, and wondering what he can find in the way of excitement to pass the rest of the day.

The manager who is too busy to see a good salesman is missing a lot, and he is not awake to his own best interests or to his firm's best interests.

Here's the way one business man put the case to CANADIAN MACHINERY this week. The gentleman in question has been a success in a large way. He has made money and he has made friends, and through it all he has retained a very great deal of genuinely good human nature. He stated:

"Right now we are trying to get our selling force back into shape for the stiff work that is ahead of them for after-war trade. They have had a chance in the last few years to become soft and easy. They're not the bang-up good salesmen they were before the war. I am out looking for pointers in salesmanship, and whenever I find anything that can be passed along to our men I consider that something worth while has been accomplished. For that purpose I am spending a little more time than formerly in receiving and paying very close attention to any salesman from a reputable firm that comes into our office. I listen particularly to any timely or appealing reasons he has at this time for pushing the sale of his lines. I watch to see if he has departed from the old path, and in a number of cases I have come across very good points that have a lot of common sense back of them. These I simply store away mentally, adapt them to our line of business and pass them to our salesmen as suggestions. I am finding it a very good way of gathering up a lot of new ammunition without very much effort."

Be civil to the man who is out representing his house on the road. He may be your competitor, and yet start some prospect thinking along a line that will start a sale in which you may benefit.

Don't get into the habit of telling the travelling man that you are too busy to see them. They know you are not. They might like it better if you would be frank and send out a shingle bearing the inscription, "I don't want to see you, so beat it."

We're inclined to think that the manager, who in these days of reconstruction, when lines are being re-shaped and policies put into the melting pot, has time to listen to the sales talk of the men on the road and see if he can find anything in their arguments that would strengthen the position of his own salesmen, has a breadth of vision that will bring his company well up to the top of the heap at the end of the year.

THE POSITION OF THE SMALL SHOP NOW THAT WAR WORK HAS ENDED

Editor CANADIAN MACHINERY:—

Sir,—

Montreal, Dec. 18.—There was one paragraph in the article headed as above, which appeared in your issue dated Dec. 5th, 1918, which particularly appealed to the writer, inasmuch as it appears to hit the nail on the head just about as square as it is possible to imagine. The paragraph referred to being:

"Canada does not stand in the place of a nation that has to deal in a niggardly way with the situation. It is better to blunder by two great efforts and consequent expenditures, than to court trouble by meeting the situation with the vision of a pinhead and the courage of a slacker."

Since the termination of European hostilities and cancellation of practically all munition contracts, there has been cast upon the high seas of commercial industry, hundreds of small engineering establishments, many of whom have been sawing wood, as it were, since the outbreak of the war, whilst others have not been so long employed upon the manufacture of the various parts required in the make-up of a shell or other parts required so urgently.

There is another class, however, by no means scarce, and one that is "meeting the situation with the vision of a pinhead," quite ready and more than willing to crawl into a hole, pull the hole in after him, and spend the rest of his life figuring out exactly how much he got away with, without having to make another gamble as it were, which, in any case was no gamble at all inasmuch as it was a certainty, and the most despised race track tout still claims that it is very unsportsmanlike to bet on a certainty.

It is hard to imagine any other circumstance that could possibly have brought to the surface so much talent and engineering genius, the same as the demands of the recent war has done, and in such a comparatively short time. Along the same lines of thought, it is just as difficult to imagine any other circumstance that could possibly have placed so many men in the position of acquiring sufficient money to even consider the possibility of pooling their money with that of others, and starting out as full fledged industrial organizations, and quite prepared to handle any and all of the multitudinous jobs that the larger and longer established shops were only too glad to have someone handle for them at, in many cases, princely figures.

Now the larger shops have been compelled to mark time, and in many cases lay off a large percentage of their help until such times as they are able to once more reorganize and enter upon a line of manufacture that they were formerly engaged upon, or some other peaceable line, these small fry referred to above are verging upon a state of hysteria for fear they cannot get hold of a line of manufacture that would bring returns commensurate with those of the munitions, or else for fear they have to hold their industrial establishments just so long that the profits will be eaten up by the mere fact that rent has to be paid, together with the insurance, etc.

Is it not deplorable to think that many of these men were brave enough to speculate, and pocket the certain profits so long as the other fellow was getting killed, but, immediately the other fellow became immuned from danger, so to speak, this "pin head" is painfully anxious to once more join the ranks of the "privates," and thus become relieved of any further responsibilities from an industrial standpoint.

Not many days ago the writer had occasion to visit a certain shop wherein had been employed some forty or fifty men. The present number did not amount to more than four or five. There were some twenty-five or thirty lathes, every one having a covering of some kind, and bearing silent testimony to the fact that their owner, or owners, had, to all intents and purposes, immediately upon the guns breathing their last "over there," covered each lathe with a look of remorse and a sigh of regret that the war was over.

Out of pure mechanical curiosity, one or two of the coverings were reverently raised (unseen) and in not one case had any oil or grease of any kind been applied to any part of these machines. Whether this was due to oversight or economy (?) can only be conjectured.

Would it not have been infinitely more optimistic and cheery generally, had these same machines been in the hands of the skilled mechanic, preparing them for whatever service they would ultimately have to render, rather than appearing as so many tombstones, and acting as a 100 per cent. efficient depressor on the few men that were left? Instead of four or five men, there was more than enough work for ten or a dozen bringing the machines into something like a respectable condition. None of them had been used on actual shell work, but all of them had been run by a double shift, which is invariably disastrous for the machines in a very short time. In view of this fact alone, would it not have been displaying a more optimistic spirit to have retained a few more of the men in order to make these very necessary repairs, and thus become prepared for any work that may crop up in the near future? Furthermore, these same machines would not only have then been in a more suitable condition for good work, but they would have increased very materially in value.

One has heard a lot of talk about the Government's short sightedness by not doing this, that or the other, also suggestions that something ought to be done in order to relieve the stress of numerous small shops. First of all, let us see who was really responsible for these small shops (not all by any means) coming into existence, and what was their motive. Was the motive one of patriotism, or was it because they had a keen suspicion that a considerable amount of pocket money could be made, and no risk? Did the Government ever know of their existence, and will it ever know they did exist?.

Had these shops relied upon the Government for contracts, it is a million to one that they would have been compelled to have pulled down their shingle inside forty-eight hours. The best the small shop could be expected to do was to either take a sub-contract from the larger shops, or else work upon special shell machinery, jigs, fixtures, cutters and the like.

Now all these demands have ceased, what then? Surely these small shop men were not so small minded as to think that the war was going to last for ever, though the way some have acted since the signing of the armistice, it would certainly suggest that they had received a bitter disappointment by the war ending so soon. One hears from every angle the question of what to manufacture, instead of what not to manufacture.

Upon reflection it must be clearly seen and freely admitted that there are really very few things that, once manufactured, cannot be sold. Of course, one does not wish to manufacture an inferior article, or, in fact, any article that would not be worth while, be it a machine tool, a household article or a toy. There are hundreds of articles that could be improved upon without infringing upon any patent rights, and as many more that could be manufactured with very little outlay on either equipment or stock.

Yet, the heads of many of these shops, and in many cases the owners themselves, are bemoaning the fact that there is nothing to do, which is just so much tommy rot. Surely these men do not expect a war has to be kept in progress in order that one may get a living. Now is the time more than any other that one should keep a stiff upper lip, as it were, and get particularly busy on some staple line of manufacture, and there are thousands. Then when the soldiers begin to pour into Canada they could be offered a remunerative position in many places, and thus relieve the Government somewhat of the big problem it will surely have to face. The toy industry has only been handled in a half-hearted way in Canada, the usual argument being that we cannot sell so cheaply as the foreigner, which is a question.

Automobile supplies offer another large field, likewise household utensils

MARKET DEVELOPMENTS

Pittsburgh Cuts the Price of Steel Products

Announcement Comes as a Surprise, as Such Action Was Not Anticipated Just Yet—Move Made as Concession to Head Off a Demand For Deeper Cuts at a Later Date?

THE announcement is made from Pittsburgh this week that prices at the mills there are being reduced before the period expires in which the Government controls prices. This action really has the effect of annulling Government control. The federal control was for the purpose of keeping prices from going past certain well-defined maximums, and the action of the mills in voluntarily going under these figures can be interpreted as marking the end of price control in the United States.

Indications also point to a similar course to some extent in Canada. This week steel plate is selling from the warehouse at 7c per pound, a reduction of 1 cent since last week. It has reached as high as 12 cents per pound, and it is on record that it even touched 15 cents during the war period, but that was before prices were controlled from Washington and Ottawa.

No announcement has yet been made as to what disposition will be made of the castings that are piled up around many of the machine shops that have been working on munitions orders. There are great piles of these. One Toronto shop that has 9.2 orders, has at least 50,000 of these blanks in its yards, and the chances are that they will be scrapped. Each of these castings weighs approximately 370 pounds in its rough state, so it will be seen that in this one place there will be 9,250 tons of material to be disposed of. This ought to be a great source of supply for the melters for some time. First operations on the machining of American shells have been stopped this week, and the business will be wound up about the 25th of the month. Some of the fuse contracts are still good, and they may be allowed to stand for some time.

Speedy action on the part of the Government in making readjustments in connection with contract cancellations would assist in removing traces of war from the trade as speedily as possible.

The scrap metal market is still in a poor condition. No sales are being made unless there is considerable urgency in the deal. Prices for material are very uncertain, and any quotation that is made is hardly indicative of the real strength of the market.

MONTREAL IS WAITING TO SEE WHAT THE OPEN MARKET WILL DO

Special to CANADIAN MACHINERY

MONTREAL, December 19, 1918. With the holiday season approaching, the quiet tone of all the markets is more than ever emphasized. It is anticipated that many changes will be effected shortly after the turn of the year and it is this possibility that influences the trade. Few are anxious to buy under the existing unsettled conditions, the consequence being that reconstruction is deferred in many cases. Plans are now being made to place most of the markets on an open basis, and it is this that puts the consumer in a reluctant mood. It is practically certain that some lines of steels and irons will go to a lower level, but with the high cost of production still a factor this appears to be uncertain. Copper producers intimate that a free market may mean higher prices.

Easier Market Coming

Just what the developments are to be in the steel situation after the turn of the year is at present undecided, but it is certain that existing conditions are not such as to throw a clear light on early future operations. That reduced prices are a natural outcome is generally conceded, but the extent of such decline is covered by the term moderate, which may apply in many ways. Dealers here are practically resting on their oars as they must abide in a large measure by the action of American producers. In all likelihood the market after the 1st of January will be an open one, but a guiding hand may be adopted to control what might otherwise result in a collapsing market. The situation here has few features, and buying is light. The possibility of lower prices is an influencing factor of present activity, and consumers are only covering their immediate requirements. In very few cases are dealers permitting cancellations of material and every effort is being made to keep stocks as low as possible. This is a good sign, and the effect will be to stimulate business when some adjustment, regarding a ruling for the coming quarter, has been made.

While deductions are contemplated, the situation here is relatively unchanged as dealers do not anticipate any pronounced development until after the holiday season.

Metals Quiet and Firm

The general metal market has been more or less influenced by the marking of time in the preliminary stage of readjustment, and with the various situations still under Government regulations, nothing of importance has developed. Copper is quiet, with buying confined to present needs, the knowledge that control may be removed or a new price set, prevents consumers from taking an interest in supplies for future requirements. Tin is in an undefined position with prices holding. Lower prices on lead had little effect on the market, and buying is not active. Other metals are unchanged at last week's quotation.

Supplies Moving Steadily

The developments so far since the termination of hostilities and the general cancellation of war contracts, have not been such as would indicate a return to machine tool activity on a large scale.

This does not mean that there is no market, as there is still considerable enquiry for various lines of standard tools, but that buying for future enterprise is almost nil. This, however, must be expected at the present time, owing to the coming holiday season and the uncertainty prevailing on all sides. Business here is not pronounced, nor is it very dull, but the recent pressure is no longer felt.

The supply demand is fairly steady, the bulk at present going to shipbuilding plants or firms manufacturing ship or engine equipment.

Scrap Very Quiet

It is not thought that the scrap market will show any activity until the turn of the year or until such time as the steel situation becomes more settled. The local market is in a stagnant state and dealers here report little or no business other than a light movement for immediate requirements. The quotations are nominal but unchanged, with the prospect for lower prices after the New Year's adjustment.

STEEL PLATE NOW AT THE 7c. MARK

Large Amount of Shell Castings Will Be Ready For the Scrap Pile Now.

TORONTO. — Machine tool dealers for the most part are trying to remove the traces of war from their business as rapidly as possible. This is impossible in some cases because readjustments have not yet been made, and there are a number of these following the cancellations that were made following the signing of the armistice.

Employment offices of several of the larger concerns in the city report that there are a number of men looking for work now, and that the hands leaving shell shops are not being absorbed as rapidly in other lines as they are being turned off from the shell plants.

A Big Scrap Pile

The closing down of munitions plants makes it quite certain that there is going to be a lot of steel left in this country that was intended to be turned into such shape that it could be shot toward the river Rhine. At one of the big Toronto plants where work has been going on on the 9.2 shell, CANADIAN MACHINERY was informed this morning that there would be about 50,000 forgings that would never get into the first operation. Each of these will weigh about 370 pounds. This means that there are some nine thousand and more tons of steel there that will have little value except for scrap. It will make nice material for some of the melters to secure.

Whether all the shells that have been machined since the cessation of the war will be secured or scrapped is another question. One firm is now piling large projectiles at the Exhibition grounds, Toronto, instead of sending them to shipping points as formerly. So far there has been a stack built up of some 15,000 shells there and it is being added to daily, this process continuing up until December 25.

Scrap Metal Trade

"We are sitting on the fence." That, in the words of a Toronto scrap metal dealer this morning, about sizes up the situation not only here but all over the continent. In fact there seem to be some places where there is not enough activity in sight to cause the dealers to climb up on the fence. Small sales are going through at prices considerably below the prices that have been and still are quoted. These sales have not yet become sufficiently numerous or significant to form the basis for a new set of prices. When a sale is made now there is more or less urgency in the deal. Either a dealer has an old contract that he is anxious to fill, or the seller has been stuck with a lot of material that he is very anxious to liquidate. Apart from these conditions there is no selling.

At one of the big shell shops this morning a bargain was made for two cars of copper turnings at 15¼c per pound. This is well below the level of trading values that have been recognized for some months past, and also well below the U.S. fixed price of 26½c for new metal. Even at that figure there is not a great chance for business, as the buyers are not certain where the market is going to find its new level when the price has been allowed to work out its own course free from control or regulation.

Plate Comes Down

At U.S. points this week announcement is made that there has been a revision downward of the selling prices of many lines of iron and steel, and this same tendency is working out in the quotations that have been made to the Canadian trade. Plate is one of the articles that forms a pretty fair barometer of trade in Canadian warehousing interests. When plate shows a tendency to come down it can be taken for granted that there will be a similar movement in other lines. This week prices on plate have backed down another cent per pound, to-day's quotation being 7 cents. For a short time this year plate sold from the warehouse at as high as 12 cents. After the War Trade Board at Ottawa came into existence that body refused to recognize anything over ten cents, and so it stayed at ten cents for a good many months. Immediately on the cessation of war the price began to slide, and has touched $9, 8 and $8.50 on the way to the $7 per hundred mark. If this figure represents anything approaching a final figure it will be seen that it is still far above the mark quoted at the American mills, which is a straight three cents for plate in most cases.

Making Readjustments

Many of the machine tool dealers feel that the governments can help matters considerably just now if they will make their adjustments quickly, and allow the dealers and all firms that have been engaged wholly or partially on war work to get back at once to regular lines. There are many firms turning from the munitions business that do not know for a certainty what lines they will develop, and for this reason they cannot place orders for equipment. The cost of securing the special equipment they may need is not going to deter them as much as making sure of the lines they are going to follow. Dealers are looking for a betterment in the machine tool demand when these firms have concluded their investigations and are prepared to turn definitely to something for domestic or foreign trade.

POINTS IN WEEK'S MARKETING NOTES

At one shell shop in Toronto which is still operating on American orders, it is estimated that there will be 50,000 castings that will never be taken into the machine shop. Each one of these will weigh about 370 pounds, so it will be seen that there will be well over nine thousand tons of steel scrap left at this one shop. The disposal of this material has not yet been decided upon.

—

The manufacture of American shells in Canada will end about the 25th of December. First operations in machining will be cut off this week. One firm has about 15,000 of these machined shells stored at the Toronto Exhibition grounds, delivery having been suspended at shipping point for some weeks past.

—

Employment offices report that there is an increasing number of applications made for work, both from skilled and unskilled sources.

—

Sales of scrap copper were made at 15¼ cents per pound this week, which is well under the level at which the metal has sold for some time, and also well removed from the U.S. set price of 26½ cents per pound for copper ingots.

—

Machine tool dealers urge that the Government should act quickly in the matter of making adjustments following cancellations on war work. The desire is to have all traces of war removed from trade as soon as possible.

—

Pittsburg announces several reductions in the prices of iron and steel to become effective at once. The explanation is that these are concessions made with the idea of protecting the steel market against any decided run on price schedules. Plate is quoted at 3 cents per pound.

—

Jobbers in Canadian points put the price of steel plate at $7 per hundred. This is a drop from varying prices, which have reached about as high as $12 per hundred during the year. Indications are that it may drop still farther here.

PITTSBURGH REPORTS THAT IRON AND STEEL PRICES COME DOWN

Special to CANADIAN MACHINERY

PITTSBURGH, Pa., Dec. 19—The iron and steel industry is reducing prices, $3 a ton on pig iron, $4 on unfinished steel, except rods, and $4 to $6 per net ton on most finished steel products, wire being an exception.

While our previous reports have reflected an expectation that producers would make a strong effort to maintain existing prices, the present reductions do not run counter to that principle. The reductions are, in essence, an effort to maintain prices, slight concessions being made for the purpose of meeting the situation and reducing the tendency to cut prices deeply. The trade was disposed to maintain Government prices because it did not see that it could find a good stopping place in the decline that would have to come sooner or later. Means have been found, however, for establishing a slightly reduced level, and the question now is how long the reduced level will hold. The theory is that it will hold longer than the full Government prices would have held.

The new level is produced by the ingenious device of the general committee of the American Iron and Steel Institute preparing a schedule of reductions, to be submitted to the War Industries Board as a basis for Government prices for the first quarter, and upon the Board's refusal to consider the matter, announcing the schedule in the newspapers as representing the views of the trade. There is no doubt that when the schedule of reductions was prepared it was known that there was scarcely any possibility of the War Industries Board naming any prices to obtain after the present quarter.

Old and New Prices

The reductions are as follows: Pig iron, $3 per gross ton; Bessemer, $35.20 to $32.20; basic, $33 to $30; No. 2 foundry (1.75 to 2.25 per cent. silicon), $34 to $31; malleable, $34.50 to $31.50; forge, $33 to $30; unfinished steel, $4 per gross ton; billets, $47.50 to $43.50; sheet bars and small billets, $51 to $47; and slabs, $50 to $46; rods being unchanged at $57; plates, 3.25c to 3c., or $5 a net ton; shapes, 3c to 2.80c; bars, 2.90c to 2.70c; blue annealed sheets .10 gauge, 4.25c to 3.95c; black sheets .28 gauge, 5c to 4.70c; galvanized sheets, 28 gauge, 6.25c to 6.05c; tin plates, $7.75 to $7.35; standard steel pipe, three points or $6 a net ton, from 51 per cent. to 54 per cent. basing discount.

No change is made in wire products as the wire mills had complained that their costs were particularly high. Various steel products are to be reduced in proportion to the basic material to which they are cognate. How far this will be carried out remains to be seen. Thus if hoops and bands were reduced from 3.50c to 3.30c there would be a reduction of $4 a ton, the same as is made in bars, but hoops being a more finished product might perhaps be entitled to a larger reduction.

At this writing nearly all the steel makers have announced reduced prices in conformity with the schedule, but applying only on new sales for delivery after this month. The blast furnaces have shown an indisposition to reduce their asking prices at once, but, of course, will do so eventually. There is so little enquiry before them, except for practically spot shipments, that there is no particular occasion to reduce prices suddenly. So far as actual transactions are concerned the market is perhaps properly quotable at the old level, but undoubtedly a good buyer prepared to take a round tonnage could purchase at the reduced figures.

Bearing on Contracts.

The pig iron and steel producers are all insisting that the reductions do not apply on contracts, that they will expect customers to take out material at full contract prices. As to this the customers will doubtless have something to say and the producers will probably have afterthoughts. In previous market declines some contracts have stood, others have been revised. Pig iron contracts usually stand, as do contracts for unfinished steel. Finished steel for definite jobs of construction, such as shapes for buildings and bridges, plates for steel cars, line pipe for pipe lines, are ordinarily in the form of irrevocable contracts. Contracts with manufacturing consumers and jobbers have frequently been subject to revision. When occupying this attitude as to holding customers to contracts, producers do not like to be reminded of the fact that if their declared program had been carried out, of the reductions being recommended to the War Industries Board and the Board naming them as Government prices for the first quarter, the Government regulation would have required the revision of many contracts. According to the Government regulation promulgated December 28, 1917, and repeated at intervals afterwards, all contracts after that date had to be so written and interpreted that the invoice price should not be above the Government price at time of shipment. As the War Industries Board is not making the prices the producers are relieved of the regulation, but according to the appearance of things the producers desired the Board to name the reduced prices and it was the Board that refused to do so.

Buying Is Light

Price reductions never stimulate buying, at least at the outset, and the iron and steel market has been particularly quiet in the past week. There is fairly heavy pressure for deliveries of finished steel on some contracts, but only by consumers who can dispose of their finished products at once and encounter practically no risk by having material on their hands in a declining market. During the war steel was very scarce and upon its conclusion there is naturally considerable call for steel in certain quarters, but there is no well rounded out consumption of steel sufficient to engage the full capacity. Mills are, moreover, feeling cancellations of Government orders to a greater extent than in the first three or four weeks after the signing of the armistice.

The future of the iron and steel market depends upon the development of regular investment buying, through new buildings, bridges, factories, etc., being projected. The investors have more to wait for than a reduction in iron and steel prices, for in carrying out their projects they must buy other materials also, and they must wait for them to come down. It is clearly understood that one motive actuating the iron and steel producers to reduce prices promptly was that of setting a good example to sellers of other commodities, to induce them to reduce prices also. Then the labor situation must be improved before much work can be undertaken. Premiums for labor must disappear and men must be willing to put in a full day's work for a day's pay. These readjustments will require some time still, but there are many observers who think that within three months' time conditions will be such as to encourage investors to go ahead with new projects.

SCRAP MARKET STILL STAYS IN A VERY LISTLESS CONDITION

THE scrap metal market is in a listless condition.

Pittsburgh.—There is practically no demand for scrap from consumers, the market being wholly confined to the dealers, and in their case the only demand seems to be for small lots to finish up contracts which expire at the end of the year. Some of the shell blanks left on the hands of shell makers by cancellations of orders are beginning to reach the market as scrap. It is reported that the sheet steel market is plentifully supplied, and low phosphorous steel has been offered for as little as $32 a ton Prices are merely nominal in the scrap market, as there is practically no buying

Philadelphia.—The amount of business done in the scrap market is very little, prices of old material falling away generally during the last week. $25 a ton is now quoted for heavy melting steel delivered, and the various other grades are on a lower basis. The real level of prices cannot be determined, as there is a dearth of real transactions.

Cleveland.—The scrap iron interests here are looking forward hopefully to the new year for active trading to resume. It is thought probable that scrap iron will not drop as low in price as has been anticipated. The limited amount of buying that is being done just now is entirely confined to the dealers. There have been a number of shells turned on the market, which have been pierced but not machined, but even though they are better than the average melting steel, there is no demand from consumers. Melting steel is being offered at $28 with but few takers.

St. Louis.—A further drop in prices is anticipated here before the bottom is reached, as all the offers on the market are to sell, with no buyers in sight. Consumers generally are staying out of the market, and are in many cases cancelling orders for supplies. Government cancellations and foreign government business being cancelled is having its effect by leaving consumers with more scrap on their hands than they have use for. The railroads are in the market to sell scrap, and in the case of some of the roads, they are holding their stock of scrap back merely in order to avoid demoralizing prices still further. However, manufacturers of specialties who have been deprived of the ability to purchase raw material for so long, are now starting to produce, and this may have a steadying effect before long.

Chicago. — The scrap iron and steel market here is in a state of considerable weakness. The tendency is to wait till the question of price regulation has been definitely settled before making any advances on the part of the consumer. A large amount of tonnage is being cancelled, in most cases contracts made for delivery during preceding months and not yet shipped. A good deal of overbuying was resorted to early in the present quarter by steel manufacturers, they thinking that by making larger contracts they would get better deliveries. A decided effect in this country is being made by the export from Canada of turnings and other scrap from the munition plants of that country.

BUYERS OF PIG IRON WAITING FOR REMOVAL OF PRICE CONTROL

BUYERS of pig iron in the United States generally are looking for the result of the meetings of the American Iron and Steel Institute with the War Trade Board at Washington, before going into the market. The impression in the trade is that after January 1st next all Government control will cease, and leave a free market thereafter. There is a good deal of strength to the market owing to a large amount of next year's tonnage having been already contracted for. The conditions covering the United States are shown in the reports from the following leading points:

Pittsburgh.—There are plenty of enquiries for immediate deliveries, but for deliveries during the first quarter and half year are notably scarce. An enquiry for 12,000 tons was received recently, delivery to be made over the first half of next year, and a price of $40 was quoted, the deal being still in suspense. Consumers who are attempting to have unfilled portions of contracts annulled, which had been allotted to them for war purposes, are not meeting with success. They are being granted a suspension of shipments, but their obligation to take all the steel allotted to them still holds.

Chicago.—The market is practically moribund here, there being no buying at present. Melters are even refusing offers of consignment of iron for immediate use. Inquiries for export are increasing, and some orders have been booked for shipment to Japan and Italy. The matter of price fixing for the first and second quarters of next year once disposed of the market will become active, as melters who have not their required tonnage on hand will be seeking it.

Philadelphia.—Sales in the eastern district have been dropping off during the last week, only a few small lots having been sold for immediate and first quarter delivery. Although contract cancellations are in demand furnaces are sticking to their position, and are refusing to make any cancellations where the contracts are binding. Owing to a large number of complaints being made by consumers about the present differential on manganese content, in some cases furnaces are waiving the differential. This is only in cases where the manganese content is low.

Buffalo.—Opinion here is that prices are likely to remain at their present level for some time to come. It is thought that some of the furnaces remote from the Great Lakes will have to shut down, as they are said to be making not more than a dollar a ton on their product. No cancellations are being allowed by furnaces here, but in some cases adjustments have been made, such as changing delivery dates, or substitutions made. The Canadian price of pig iron is from $6 to $8 above the Buffalo price. It is the general opinion that after the first of the year there will be an open market.

Birmingham.—There are quite a few offers being made by foreign buyers, Japan and Italy in particular, for large tonnages. Some small cancellations have been received in this territory, but these have been covered by domestic consumers buying small lots. The slow output at coal and ore mines, and the same conditions at limestone and dolomite quarries is keeping back production here, no improvement being shown in this direction.

St. Louis.—The situation here is adjusting itself in a manner which is surprising the most optimistic. Cancellations are being strictly forbidden by southern furnace interests, who recommend their purchasers to dispose of their surplus by resale, which method they believe will tend to keep prices firmer than if the melters disposed of the stock themselves. There is a large demand through this territory for pig iron from stovemakers, etc., who have been unable to get pig iron for quite a long time, and the demand for finished articles is enormous. It is believed this will keep foundries busy till well into 1919.

Cleveland. — Large sales have been made through the week, in the form of allocations placed through the committee on pig iron ore and lake transportation through this city. The quantities called for were from 25,000 to 30,000 tons of foundry iron for delivery at points on the Pacific Coast, and immediate shipment was requested. This was all for Japanese interests. Inquiries for malleable and foundry iron are fairly numerous, one of them being for 5,000 tons for the first half of the year. There is a large requirement for the first half of the year for the automobile trade, but they are expected to go very cautiously. Contracts entered into formally are being refused cancellation.

THE TRAINING OF FOREMEN
By D. STREET

One of three methods is usually adopted by firms when choosing a foreman—the position is advertised, a nominee of the retiring foreman is promoted, or advancement is by seniority. To promote anyone to a responsible position because of long service is not wise, as, although a man may be an excellent craftsman, and of good character, unless he has certain natural attributes, he will not make an efficient foreman; nor is it wise to accept the advice of a retiring foreman, because he may be actuated primarily by friendship, and with the best intention his opinion will probably be biassed. Advertisement appears to be the fairest and wisest way, although even then there is no guarantee that the best man will be chosen. It is surprising that we have no recognized way of training ambitious craftsmen who aspire to foremanships. There are essential virtues of a good virtue that cannot be imparted, such as tact and firmness, but they can be greatly strengthened, and many of the qualities that make a successful foreman can be taught. It is as important to have highly qualified men as foreman in our workshops as it is to have competent non-commissioned officers in an army. They have, to a great extent, a direct influence on increasing the productivity of both men and machines, and, on the other hand, if they are unsuitable, they are a source of continual irritation among the workmen, which generally ends in strikes. A great many strikes could be traced to the pin-pricking policy of a foreman engendering discontent. There are very few men who, after holding a subordinate position for many years, and never having studied what makes the capable leader, can withstand the temptation of unduly asserting themselves when placed in a position of authority. The problem is to a considerable degree psychological, and a proof that no great change can safely be effected in a man's position of the incompetent foreman is that he exerts an influence on the apprentices which affects their whole career. Anyone who has had experience of workshop life knows that the character and conduct of the boys are moulded by those around them. It is during the impressionable years of the teens that character is formed, and a good foreman, by surrounding himself with good craftsmen, may do a very real service to the state.

The appointment of a new foreman is always experimental, but very often, for a considerable time after the change, the output of the department is reduced, and there is a great deal of dislocation that could be avoided. The promoted man is only an apprentice in leadership, and has to become proficient through making blunders and gaining experience.

The ideal foreman has business abilities and an irreproachable character, a first-class technical education, and a high degree of skill as a craftsman. There are, however, few ideal foremen and very many employers ignore the point of character, and either show a preference for a skilled man with small business ability, or a good business man and organizer, who is an indifferent craftsman. There is no reason why the average foreman should not approach the ideal, and it is regrettable that our technical institutes do not have courses of training suitable for ambitious young mechanics who aspire to become foremen. It is usually the best class of lads and young men who attend technical classes, and although the diploma which they may receive is a guarantee of years of application and a knowledge of principles which is invaluable, the man may be still unsuitable for a foremanship. It would appear to be desirable either to have a course for a supplementary diploma on "Foremanship," or to include lectures on organizing and the best way of dealing with men in the ordinary diploma course. Whatever department of life is considered, it is not always the most brilliant scholars who are the best leaders, or who make an enduring mark, but those men who have the inherent or acquired qualities which enable them to restrain wisely, and, when commanding, to win respect. It is a very great advantage for the foreman to be able to express himself, and to explain in a lucid way what he wants, and the best way of doing it. To convey one's ideas to others is largely a matter of education, as clearness of expression is not altogether a gift. It may be contended that the difficulty of procuring good lecturers would be great, but there are men in every large technical school eminently qualified to give instruction in organization. It would be a wise procedure for large firms to run courses of lectures for their foremen during the winter months, and such lectures could be delivered by outside scholars and by managers who have had a wide experience.

The labor situation in Northern Ontario is already showing symptoms of improvement, according to the "Advance." Several hundred men have come into the Porcupine during the last few weeks, and more are coming every day.

WHAT ARE CHANCES FOR BRAZIL'S TRADE?

Nearly all the electrical machinery now supplied to Brazil comes from the United States, although, before the war, a good deal was imported from Germany. The reason for Great Britain's poor showing can only be that our manufacturers have not sufficiently pushed the sale through suitable agents. The British Chamber of Commerce of Sao Paulo will be glad to place British exporters of electrical machinery, or any other goods, in touch with the right class of agents.

Files

The Americans have captured the file trade. Some years ago the files were supplied from Great Britain, but the Germans took the trade away in spite of the poor quality of their goods. The Americans followed the lead of the Germans, but produced a better quality file, with better packing, and captured the trade. Customs duties on files are paid according to weight; consequently the demand is for what is now known as "light weight" files. The Americans pack their files in neat cardboard boxes of half-dozen, dozen or more, depending on the sizes, whereas British makers continue to wrap their files in paper parcels in the old-fashioned manner, which parcels get torn in transit, the ends of the files stick out, rust and generally are less easy to handle.

AN INTERESTING JUDGMENT

A case of interest to all those who have occasion to entrust repairs to an engineering firm, without making a definite contract, was decided at Montreal last week, by Mr. Justice McLennan, sitting in the Admiralty Court. This was an appeal taken by the owners of the "Susquehanna" from a judgment in favor of the Canadian Vickers, for the cost of repairs made to this vessel. The amount claimed was $52,983.34, and the appeal judge reduced this amount by $17,000. The repairing firm's statement showed that material plus 5% handling charges came to $6,665.43, and the labor to $14,905.73, and the total claim amounted to $53,541.21.

After pointing out items charged to "overhead expense" and one of 47.3% net profit, the judge stated that the burden was on the plaintiff to establish that its account represented the fair market value of the repairs. If the cost were definitely ascertained a net profit of 12½% would have been fair and reasonable. If the average of the overhead charges to others as just stated was added to the charges for labor, and a net profit of 12½% added to cost of material, labor and overhead so ascertained, the total would be under $35,000, which was the amount estimated approximately by the plaintiff's works manager, and manager before the work was undertaken. The judgment was in favor of the appellants for $35,080.

It is unusual to find a company of the standing of the Canadian Vickers making charges which are practically exorbitant, but the judgment given in this case should serve as a useful example to other firms who are sometimes tempted to extract undue profits from clients who have no fixed contract made for the work to be done.

AIR-COMPRESSOR TROUBLES

Some time ago a small belt-driven vertical air-compressor was installed in a certain boiler-room where there was considerable dust, due to handling coal and ashes. It was necessary to extend the 1½-in. inlet pipe outside of the building. As the unloader was of a sensitive construction, and as the least bit of dirt would make the pistons stick, causing poor regulation, considerable power was wasted because of the safety valve on the receiver releasing continually.

It was desired to connect the pipe as direct to the compressor and with as few fittings as possible, which located the end of the suction pipe between the eaves of three roofs. To keep it free from water and other obstructions, a hood was made from 6-in. galvanized sheet metal pipe with a 2-in. galvanized pipe nipple. These parts were all taken from used material found about the factory. This arrangement has worked satisfactorily for about a year, and it has never been necessary to clean out to unload, nor has there been any trouble from poor regulation.—M. E.

THE POSITION OF THE SMALL SHOP

Continued from page 711

and builders' supplies, the manufacture of the latter having been at a standstill practically since the commencement of the war. Then again, what condition is eighty per cent. of the machine tools in Canada in to-day? Little better than scrap; that is, those tools that have been employed upon munitions and the like. In order to bring them to within fifty per cent. of what they formerly were means a lot of work, and it will cost money, but have they not earned money? Good money, too. If these "pinheads" think for one moment that because the war has ended, that they must now jump their traces, and do ultimately get out of business, then business has certainly profited greatly by the termination of the war, inasmuch as it has got rid of these "pinheads," who, having the courage of a slacker, has lived up to the old, old adage, "He who fights and runs away, lives to fight another day."

Steel Grip

Gloves and Mittens

No. 605
$10.20 per doz. pairs (or all lefts or rights)

No. 674
$10.20 per doz. pairs

No. 680—Reversible Gauntlet Mitten. Can be worn on either hand. Price, $10.80 per dozen pairs (24 mittens).

Give so much extra **wear** that they're the most economical gloves and mittens you can buy.

For sandblasters, shipbuilders, pig iron handlers, chain handlers, scrap handlers, smelters, miners, grinders, chippers, etc.

Steel-Grip Industrial Gloves and Mittens give this **extra** wear because of their patented Steel-Grip reinforcement of palm, fingers and thumb, and steel-sewed seams.

And this patented Steel-Grip reinforcing does not interfere with flexibility or comfort.

It **does** insure a longer life for gloves and mittens.

It **does** insure complete protection for the hands of workmen.

The steel sewing makes the gloves positively rip-proof.

These are the strong points of Steel-Grip Gloves and Mittens. See how well they work out in actual use to the advantage of yourself and your men.

BRIDGEFORD

Meeting Service Conditions

In the Cleveland, Ohio, shops of the Erie R. R. in which these photographs were taken, service conditions demand the utmost despatch in retruing car axle journals. To handle necessarily heavy production with economy and efficiency, demands an axle lathe that will, day in and day out, stand up under the conditions imposed.

For 11 Years the

Bridgeford Heavy Axle Lathe

installed in these shops has faithfully kept up its maximum production with only the replacement of a set screw in the gear box. Averaging between 25 and 30 axles a day speaks for itself.

And Here Is the Proof:

	Min. Sec.
1. Setting up	:27
2. Turning collars	2:10
3. Rough turning	6:14
4. Finishing cut	4:20
5. Rolling	4:18
6. Polishing	2:05
7. Taking down	:29
Total	20:03

While necessarily the human element enters into production, the fact still remains that the design and construction of the lathe is responsible for the operator obtaining the production. This is because it is designed and constructed by lathe specialists who have an intimate knowledge of railway requirements and axle turning problems. Why not put *your* axle turning problems up to men who *know?*

THERMIT WELDING on all classes of work is a special feature of present activities.

Manufacturers of Steel Tanks, Air Receivers, Welded Tanks, etc.; Electric Welders, Oxy-Acetylene Welders, Boiler Repairs, Lead Burning and Thermit Welding.

If You Need a
POWER HAMMER

of uncommon strength throughout — a hammer constructed to deliver work of surpassing quality in great quantity, and to keep everlastingly at it—

You Need Jardine's

Note a few particulars:

Hammer slide is a steel casting; so is the ram, and connecting bolts for the ram are machined from solid steel bar.

Hammer and anvil dies of properly tempered, highest grade tool steel are held in machine seats by tapered keys in the ram and anvil block, so there's no need to put taper on the dies.

Jardine's Canadian Giant Power Hammer has never failed.

LINK-BELT

FOR EVERY PURPOSE

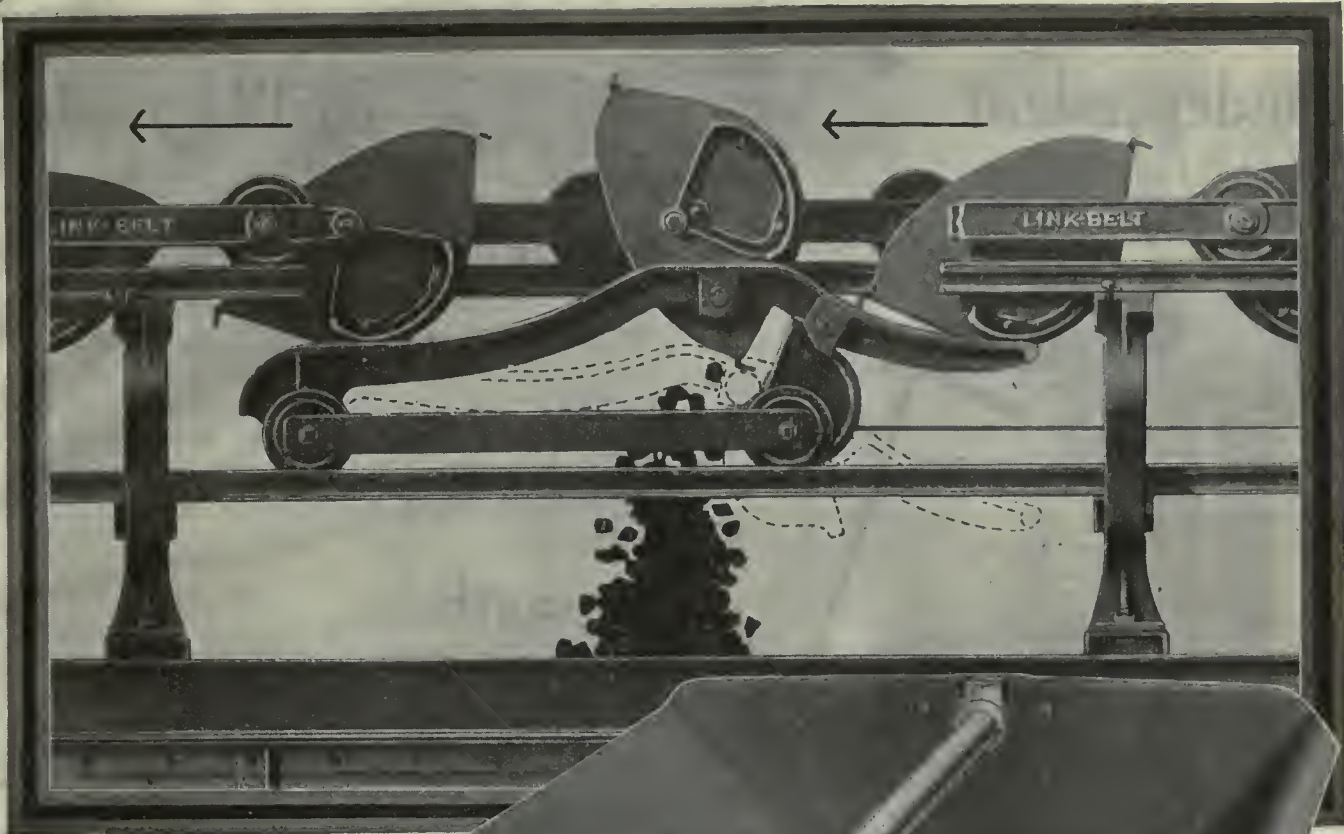
Whether your problem is one of power transmission, elevating or conveying, we have a type of Link-Belt especially designed for the purpose.

And when we say "especially designed," we mean it. For our engineers have spent years in the study of the peculiar conditions and requirements which various industries place upon Link-Belt. Each type has been designed not with the thought of how cheaply it can be made, but how perfectly it can serve its purpose. We show a few types of Link-Belt above. Our catalog shows many others. Send for a copy.

CANADIAN LINK-BELT COMPANY, LTD.

265 West Wellington St., Toronto

MADE AND CARRIED IN STOCK IN CANADA



Detail of Bucket

Upper Driving Corner

Elevates, Conveys and Automatically Dumps Coal, Ashes, etc.

THE Peck Carrier represents positively the last word in coal and ash handling equipment. The coal is not scraped but **carried** in overlapping, pivoted buckets, from the cars to the bunkers over the boilers.

The elevating, conveying and automatic dumping of the coal is all accomplished by one piece of equipment. There are no transfers needed. The buckets are supported on rollers. Friction is largely eliminated and power required is reduced to a minimum. Operates silently and without vibration.

The Peck Carrier is also used for the handling of cement, crushed stone, gravel, etc. Catalog mailed on request.

INTERNAL AND SURFACE GRINDING

If you do surface or internal grinding one of these three will handle your work to best advantage.

The CYLINDER GRINDER will take care of all work that cannot be rotated to advantage, such as two, four or six cylinders en bloc, and awkward large sizes castings of any material.

The INTERNAL GRINDER produces absolutely accurate holes, either straight or taper, in hardened steel, iron or bronze. It is ideal on bushings, gears, collars, ball bearing races and a thousand other parts, where an accuracy and production are essential.

The SURFACE GRINDER delivers at a commercial rate a mirror finish on keys, rings, cutters, dies, discs, collars; in fact any shaped part whose size is within the capacity of the chuck.

6 ways you'll profit by introducing

DENNISTEEL

MADE IN CANADA

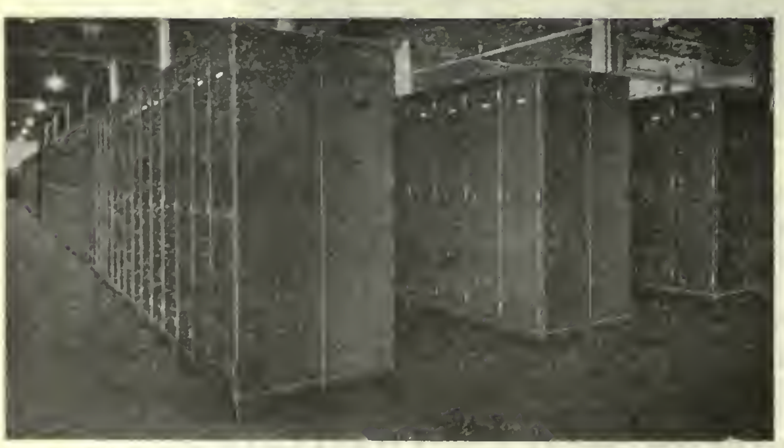
Lockers, Cabinets and Shelving

DENNISTEEL Material Cabinet. Saves costly parts and tools from damage. Saves men's time hunting for articles needed. Keeps your expensive stock safe from pilferers.

The day you begin to use DENNISTEEL Equipment you take positive action in the direction of

1. Fire Prevention
2. Increased Efficiency
3. Time Saving
4. Space Saving
5. Stock Saving
6. Money Saving

DENNISTEEL Shelving (standardized). Takes proper care of stock, preventing careless handling. 25% more storage space than wood shelves. Makes stock-taking simple. Adjustable to requirements. Will carry heaviest loads. Reasonable in cost and FIREPROOF. Ask for special shelving folder.



DENNISTEEL Wardrobe Lockers represent the highest type available. They cost a trifle more than others, but ultimate cost is less. Used by leading Canadian firms and corporations, because they stand up in service. Write for three-color folder on lockers.

DENNISTEEL equipment is used by all railroads and leading factories and industrial plants throughout Canada. DENNISTEEL is standard—not the cheapest but the best—and this applies to design, material, construction, finish and durability.

DENNISTEEL is fireproof, non-warping, cannot split, crack or rot, takes up little space, lasts a lifetime, keeps things tidy, is reasonable in cost, never needs repairs.

We make everything in modern shop equipment. including lockers, in all styles, standardized shelving, cabinets of every kind, tool stands, partitions, chairs and stools, draftsmen's desks, and a complete range of steel hospital equipment. Write for illustrated folders.

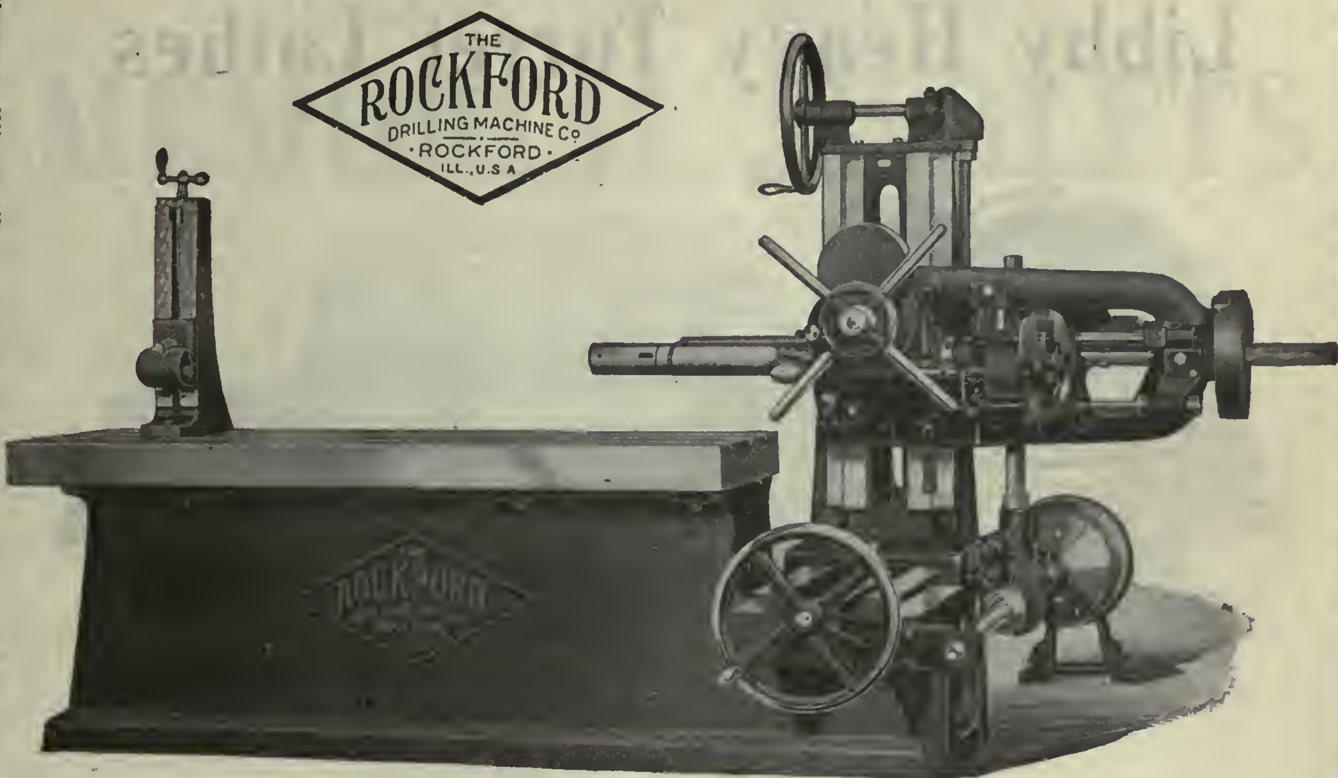
THE HOWARD PNEUMATIC ENGINEERING CO. LTD.
EASTBOURNE, *ENGLAND.*
ESTABLISHED 1904



A Horizontal Boring Machine

For Heavy Duty or Fine Jig Work

This wide range machine has the strength and rigidity to drive 2-inch high-speed drills to capacity and boring tools up to 8 inches and over, but is so carefully balanced and nicely adjusted as to adapt it equally well to the finest jig work.

Lateral and vertical adjustment of the head to permit the spindle to operate anywhere over a surface 18 by 36 inches; spindle of special forged steel, ground to size, has long nose with 5/8 x 5/8 slot in the end and is provided with ball thrust bearings. Steel gears provide nine different speeds without stopping the machine and the automatic trip guards against the spindle being advanced beyond its intended range of movement.

Six styles of drive: 2, 3 and 4-step cone with back gears, and 5, 4 and 3-inch belt respectively; gear box with tight and loose pulley; variable speed motor, directly connected, and constant speed motor with gear box (as illustrated). Complete description in Circular R-1.

Say you want all particulars.

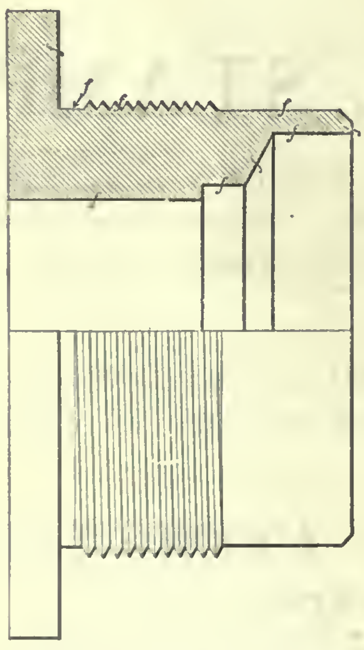
The New Britain Machine Company

New Britain, Conn. U.S.A.



Automobile Steering Case Adjusting Cap

Seven Operations at One Setting
—110 Times Per Hour

THIS is a **typical,** rather than unusual, example of the sort of work on which "New Britain" automatics are rendering yeoman service in the defense against the forces of advancing costs.

Seven distinct operations—turning, boring, counterboring, reaming, facing, necking and threading—are involved in machining this automobile part. **The series is completed and a finished piece delivered every thirty-three seconds!**

The expression **"All Operations Simultaneous and Automatic"** is indicative of the extent to which idle time and needless manual attention have been eliminated in the design of the "New Britain." Operator's **sole duty** is the insertion and removal of work.

A further advantage of these machines—**especially important at this time of labor scarcity**—is their capacity for successful operation by unskilled workers.

To those accustomed to handling such work in a turret lathe or hand screw machine, the radical saving to be effected by the adoption of "New Britain-Automatic" methods will be evident.

We stand ready to investigate the possibilities in your case.

Obligation? None whatever.

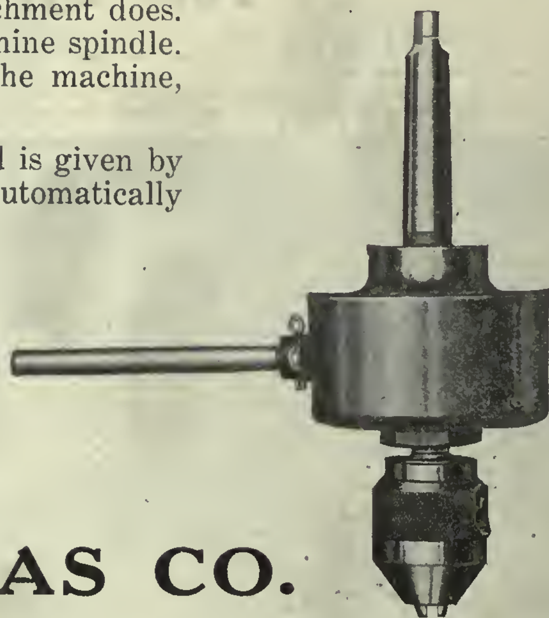
"B-T" Reverse Tapping Attachment

Saves Tap, Time and Trouble

That is what the "B-T" Reverse Tapping Attachment does. It eliminates the necessity of reversing the machine spindle. Simply raising the spindle reverses the tap—the machine, meanwhile, goes ahead at full forward speed.

A reverse speed twice that of the tapping speed is given by an internal gear drive. It is friction driven—automatically adjusted by the amount of pressure the operator puts on the drill spindle. It saves taps, trouble, time and money.

Can also be had with positive drive. Both plain and friction chucks are fitted with jaws to grip round and square end of tap.

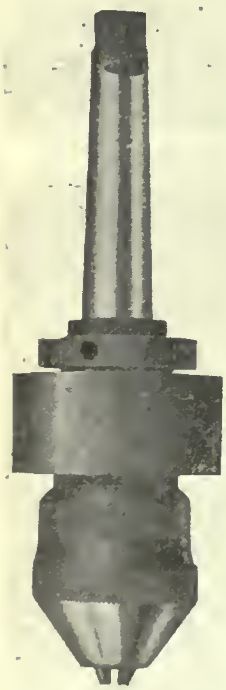


Get the details—In our Bulletin.
Write to-day.

BICKNELL THOMAS CO.

GREENFIELD, MASS., U.S.A.

Another Broken Tap!



Same old story: tap running at high speed—meets hard spot in metal—strain too much for tap—*snap*—get a new tap. Happens every day unless you use

Bicknell-Thomas Friction Chucks

The instant the tap binds with a "B-T" the friction grip holding the tap slips, relieving overstrain, and prevents tap twist or breakage.
Compact; used on multiple-spindle drills and many other machines. Five sizes ⅛"—1"; either straight or Morse Taper Shanks.

How would you like to try one?

B-T THREAD LEAD INDICATOR

Exit—Spoiled Parts

Did you ever have to scrap a threaded part because of incorrect measurement in lead. Were you ever forced, during a rush job, to thread a part over again, because it didn't fit as it should?

B-T THREAD INDICATORS

enable you to get the right thread lead instantly and maintain a constant check upon it. They will detect errors of one thousandth of an inch—can be used for testing odd and even pitches, as well as internal and external threads.

BRIQUET INGOTS
for the Arts of Peace
With the war-demon chained, we hope **forever,** the arts of peace will clamor for brass and **more** brass; and every ounce that both Canada and the United States can produce will be required for railroad, marine and industrial work, at home and abroad.
BRIQUET-INGOTS
(Trade Mark)
will serve peace as they have been serving war by putting into meltable form thousands of tons of chips and finely-divided scrap—purified of iron and all other foreign substances.
COPPER, TOO
A later development is the purification and briquetting of copper shell-band turnings and similar copper waste. This is done, for the present, at our Chicago plant only.
Briquet-Ingots are made only by us. The name is our trade-mark and the processes and machinery patented. **Briquet-Ingots** are practically as uniformly pure and permanently solid as virgin cast ingots, though no heat and no binder are used in their manufacture.

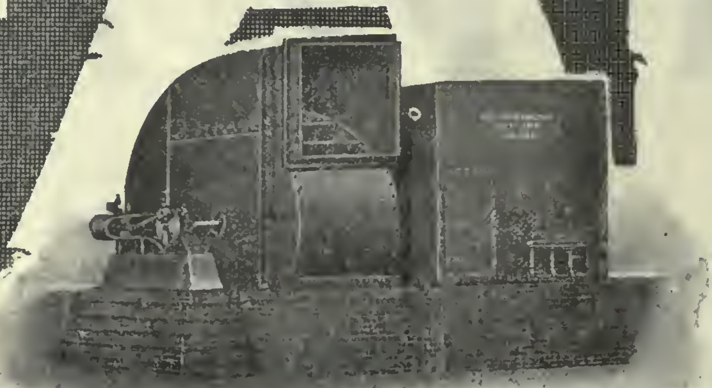
FAN



SYSTEMS

of Heating and Ventilation

Machine Shops, Foundries, Bridge Works, Woodworking Plants, Spinning Mills, Paper Mills, Auditoriums, etc., etc., are heated efficiently and economically with the Reith Fan System.

A FEW ADVANTAGES:

(1) Entire system under one man's control.

(2) Building may be heated up quickly in the morning.

(3) No leaky valves or frozen pipes around the building.

(4) Heater coils will stand pressure of 100 lbs. and over.

(5) System may be used for cooling in hot weather.

Take advantage of our experience and let our engineers solve your heating problem for you.

These Items Spell

QUALITY

FIRST COST + OPERATING COST + MAINTENANCE COST + ADAPTABILITY + EFFICIENCY + EFFECT ON PRODUCTION + SATISFACTION

in Lamps

FIRST COST alone is **never** the criterion by which to gauge QUALITY. There is **no** "Quality" that does not contain **most** of these elements---LACO LAMPS contain them **all.** You may hesitate at the larger investment, but don't let the bogey of "First Cost" run away with your better judgment. If you **want** QUALITY in your purchase, you **must** pay for it. Analyze the LACO standard:---

First Cost--slightly higher than the best "ordinary" lamp.

Operating Cost Lower—30 to 50% less current consumption per 1,000 hours for same quantity of light. One official test, for instance, showed 4 Laco Lamps burning 936 watts, gave the same light as 4 competitive lamps burning 1443 watts.

Maintenance Cost Lower—25 to 40% longer life. (Replacement cost of 4 brands in same 1000-hour test averaged $12.68—LACO none.) Guaranteed life of ordinary 1000 watt lamp is 1000 hours, but actually averages much less. LACO Lamps are *guaranteed* for 1500 hours' life, and users frequently get two to three times this service; we can quote LACO Lamps that lived over 10,000 hours.

Adaptability—LACO Tungsten Lamps are made in sizes up to 60 watt; LACO Nitro are made in sizes 60, 100, 200, 250, 300, 350, 400, 500, 750 and 1000 watt—a LACO size for every need.

Efficiency—LACO Lamps are guaranteed to give the candle-power U.S. standard specifications provide. They furnish a clear, brilliant, colour-true, daylight ray.

LACO LAMPS

Effect on Production—
Government statistics have proved that the LACO quality of lighting will increase workers' earnings; one example alone showed 11.4%.

Satisfaction--Is found in hundreds of letters from big operators in every line of business all over the country, telling their experience with LACO LAMPS. Read examples quoted.

Without cost to you—our nearest office will have official laboratory tests made of your lamps to prove our claims. Our lighting engineers will plan and submit an installation to meet your exact requirements in the best and most economical way.

Toronto.

Toronto, Nov. 10th, 1917.

Gentlemen:

Our store has been equipped throughout with your Laco Nitrogen filled Lamps since September, 1914 with very satisfactory results. During that time we have kept a very close record of the life of the various sizes in use and the following is a list of the average hours burning, taken from records kept since 1914.

500 Watt average 2766 hours. 400 Watt average 2632
350 " " 1600 " 250 " " 2306
100 " " 1200 "

We have also installed several of your Nitro Lamps in our Toronto and Regina Mail Order Buildings along with your 40 and 60 Watt Tungsten Lamps with equally good results.

Trusting this information will be of service to you, we are

Yours very truly,
The Robert Simpson Co.

STRENGTH

to match the producing power of your Heavy Duty Drill Presses

CELFOR

HIGH SPEED TWIST DRILLS

No longer is it necessary to "go easy" with your High Speed, Heavy Duty Drill Presses for fear of burning up your drills.

No pace is too great for Celfor Drills. The chief reason is in the forging process by which the "Celfor" is made. The original grain or fibre is kept intact; there is no deep milling. Instead, the grain runs with the twist. So strong is the flute and so great the cutting powers that an over-size shank is required to utilize them.

There are other reasons why the call for the "Celfor" is growing constantly louder as the need for production increases. Let us show you.

More Necessary Now Than Ever—

The war taught us all many things about gages and gaging systems. Gaging made possible the greatest production of machine shop products ever attained in the Dominion.

And now that peace is here the advantages of gaging will be more necessary than ever.

Johansson Combination Gage Blocks give you a standard that permits you to maintain your gages in the face of inevitable wear. They are in use by practically all big toolrooms.

Johansson Adjustable Limit Snap Gages are put into the hands of operators and inspectors after being carefully set and sealed to the "go" and "not go" sizes of the work to be gaged. They prevent the attempt to work to "absolute dimension," and can be reset as often as is necessary to keep them to size—when sizes change, when limits change or when wear takes place.

Twenty-one sizes give all dimensions up to 12 inches.

Be sure to get our new catalog and discounts.

A Projecting Set Screw Is a Menace!

It Puts Your Life in Danger

You may be working around the shaft, absorbed in the work you are doing, when, without warning, a projecting screw will get mixed up with your clothing and —you're in danger of losing your life. The projecting screw looks innocent enough, but it's a dangerous thing to get near when it's in a revolving shaft. This is no theoretical case. In Illinois, in one year, 100 men were killed or crippled for life due to set screw accidents. In fact, a law is now in effect in many states forbidding the use of projecting set screws on revolving shafts.

To positively prevent all accidents of the kind illustrated and to secure perfect set screw results, you should use

ALLEN SAFETY SET SCREWS

Made from special steel bars. Strong and well constructed. Will not mushroom in the hole. The hexagon hollow stays hexagon. It won't stretch and get out of shape. It stands all kinds of pressure. You can put your whole strength into turning the screw and not harm it in the least, though you *might* break the wrench. Allen Screws are always easy to take out. Nothing about them to wear.

Scientifically made. Every screw of a certain size, exactly the same. Made by a patented process, strengthening the metal over 30%, which together with their thickness at the point, makes them the strongest ever. They are quality screws, screws you should use if you want to prevent set screw accidents, troubles, delays and expenses.

Get Samples—Put Them to the Test.

We'll gladly send you samples which you can put to any strength test you want. The test will convince you that while you may have seen screws that **looked** like Allen screws, you have never seen any with their strength and pressure-resisting qualities. Write for catalog and price list.

WELLAND SECTION

The City of Welland

is Forging Ahead

Twenty-five big industries of continental reputation have proved this during the last five years.

Every year in Welland is a record year—until the next one arrives. This is certainly true of the value of our manufactured products, which last year reached the astounding total of $28,642,390, an increase of very nearly fifty per cent. over the previous year, which, in turn, had shown almost as large a proportion of increase over the year 1915.

Do not these figures lend a new weight of proof to the common prophecy that the city of Welland is destined to be one of the first manufacturing cities of Ontario, and the zone of the Welland Ship Canal the **Workshop of the Dominion?**

Power Rates—Welland is the industrial hub of the Niagara peninsula where an unlimited amount of electric power is available and sold at competitive prices, owing to the numerous power companies represented there.

Every factory in Welland is driven by electric power supplied by the Ontario Power Company, of Niagara Falls, which is about twelve miles east of Welland, or from the Dominion Power Company of DeCew Falls, which is about twelve miles north of Welland. The fact that we have competitive companies operating in this district gives us competitive prices on power.

Cheapest Power in Canada

Unrivalled Rail Facilities

Lake Shipping Advantages

Lake Shipping: Welland is situated on the Welland Canal, the great marine highway, between tide water and the Canadian North-West, with daily freight service both ways.

Railroad Rates: Rates from Welland to the North-West and Pacific Coast, all rail, are the same as from all other manufacturing points in Eastern Canada lying between the Detroit River and Montreal. These rates are fixed by the Board of Railway Commissioners for Canada.

On account of the close proximity to the border, Welland is in the Buffalo switching group, and takes the Buffalo rates from the east and south, and enjoys quick delivery on all raw material imported from the United States.

The fact that all of these roads centre here creates competition, and is the biggest lever the manufacturers have for securing efficient service from the railroads.

The seven railroads are as follows: **Grand Trunk, Michigan Central, Toronto, Hamilton and Buffalo; Canadian Northern, Pere Marquette, Canadian Pacific, Wabash.**

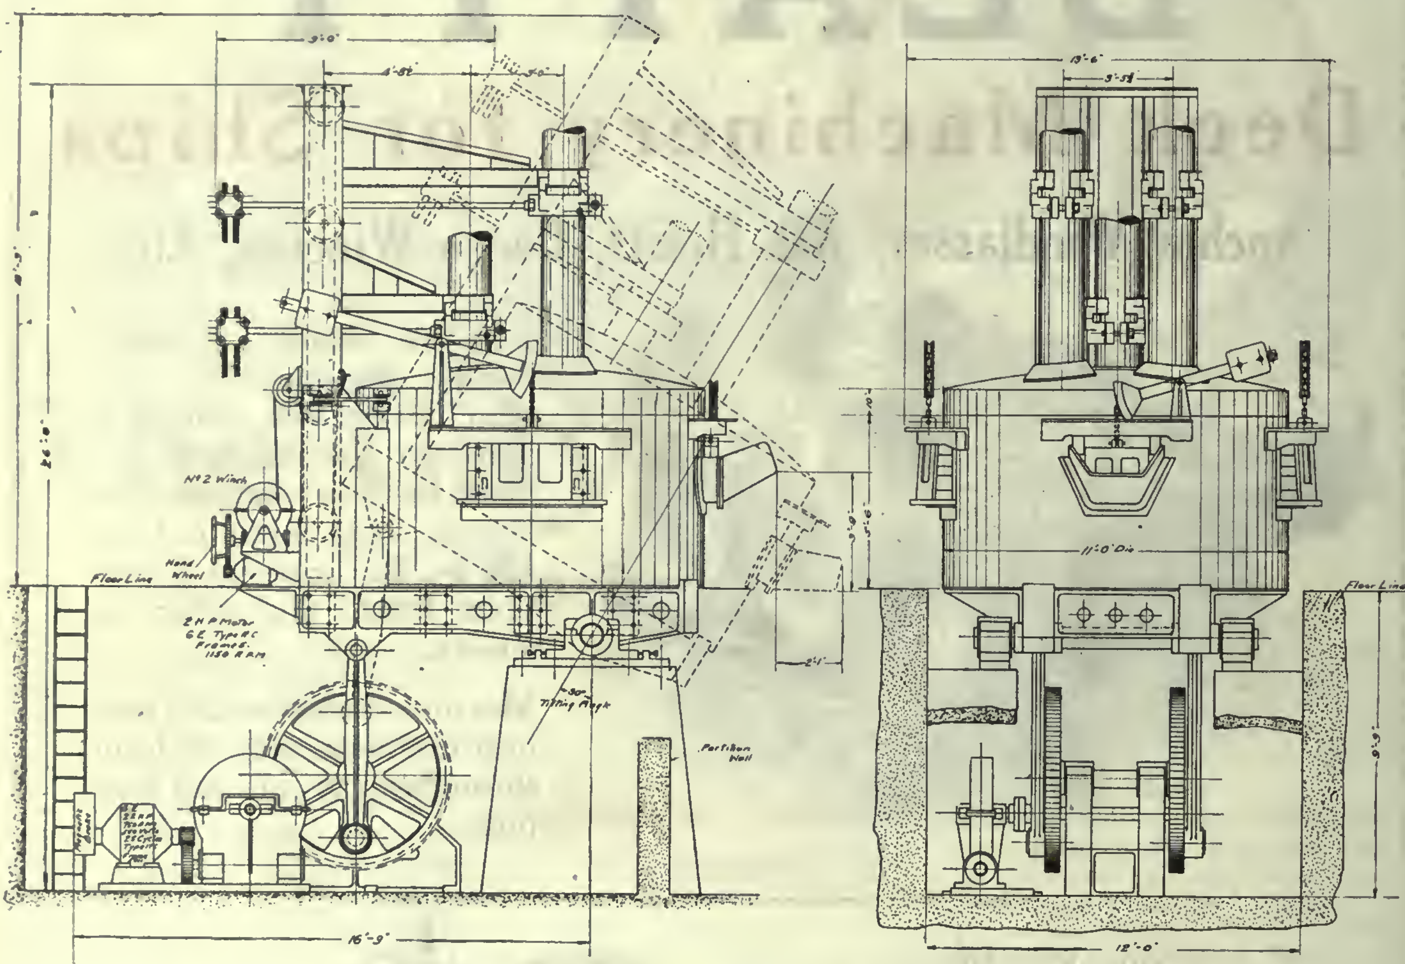
Volta Electric Steel Furnaces



6-TON 3-PHASE TILTING FURNACE

Sales of Electric Steel Furnaces during the period of the European War, for special steels and steel castings, have been phenomenal, the main reason being the superiority of electric steel over other steels and the adaptability of the electric furnace to use all kinds of scrap and practically no pig iron.

Steel specifications in the future will call for chemical and physical requirements in steel, which can be obtained in electric furnace practice with little additional cost over ordinary steel.

The furnace here shown is the result of close observation on our part of the many different types in operation since the first electric steel furnace was installed, and the criticism of different users of electric steel furnaces. It is in many respects equal and in a number of ways superior to any other type at present in use.

This furnace is simple, built of the strongest materials to ensure solidity, and will produce a maximum tonnage at a minimum power cost.

Prospective customers would do well to get complete information on this furnace, and our technical service, which we offer free, will be of material assistance in working out the various details which occur in connection with electric furnace installations.

PRESS ADVERTISING SOLD VICTORY BONDS

BEFORE the war, bond buyers were "marked men." In number they were 40,000 in March, 1917 — this is shown by the number of purchasers of the Government War Loan of that date. But in the autumn of the same year, their number increased twenty times — to 820,000! This was the number purchasing the Victory Loan, 1917. Last month—November, 1918—over 1,000,000 persons purchased the Victory Loan, 1918!

These wonderful results were accomplished by Press Advertising.

Before the war one-half of one per cent. of our people bought bonds. Now quite twelve and one-half per cent. of our people are bond buyers!

Before the stupendous amount of $676,000,000 worth of bonds could be sold to our Canadian people in three weeks a most thorough and exhaustive campaign of education was necessary, and this campaign was carried through by advertising in the public press. The power of the printed word never had a more convincing demonstration.

By means of the printed word, through the medium of advertisements in the press of our country, the Canadian people were made to know what bonds are, the nature of their security, their attractiveness as an investment, and why the Government had to sell bonds.

Every point and feature of Victory Bonds was illustrated and described before and during the campaign—in advertisements. No argument was overlooked. No selling point was neglected.

The result is that Canadians to-day are a nation of bondholders.

They know what a convenient, safe and profitable form of investment bonds are. Instead of one man in two hundred owning bonds, now one Canadian in eight—men, women and children—owns a Government Security.

This complete transformation in the national mind and habits was brought about by advertising in the press of the nation. Press advertising has justified itself as the surest and speediest method by which a man's reason can be influenced and directed.

The Minister of Finance acknowledges this. His own words are:

> *"The wonderful success of the Loan was due in large measure to their (the press of Canada) splendid and untiring efforts during the whole of the Campaign."*

Mr. E. R. Wood, Chairman of the Dominion Executive Committee having oversight of the campaign to raise Victory Loan, 1918, said, " . . *The press publicity campaign . . . . will rank as one of the most remarkable and efficient publicity campaigns ever undertaken in any country,"* and Mr. J. H. Gundy, Vice-Chairman of the same committee, said: *"I have been selling bonds for a long time, but I never found it so easy to sell them as at this time. The reason is the splendid work the press has done. I take off my hat to the press of Canada."*

The success of Victory Loan, 1918, and the knowledge which Canadians now possess of bonds are a straight challenge to the man who doubts the power of the printed word, in the form of advertisements, to sell goods—and this applies not to bonds alone, but to the goods *you* are interested in selling.

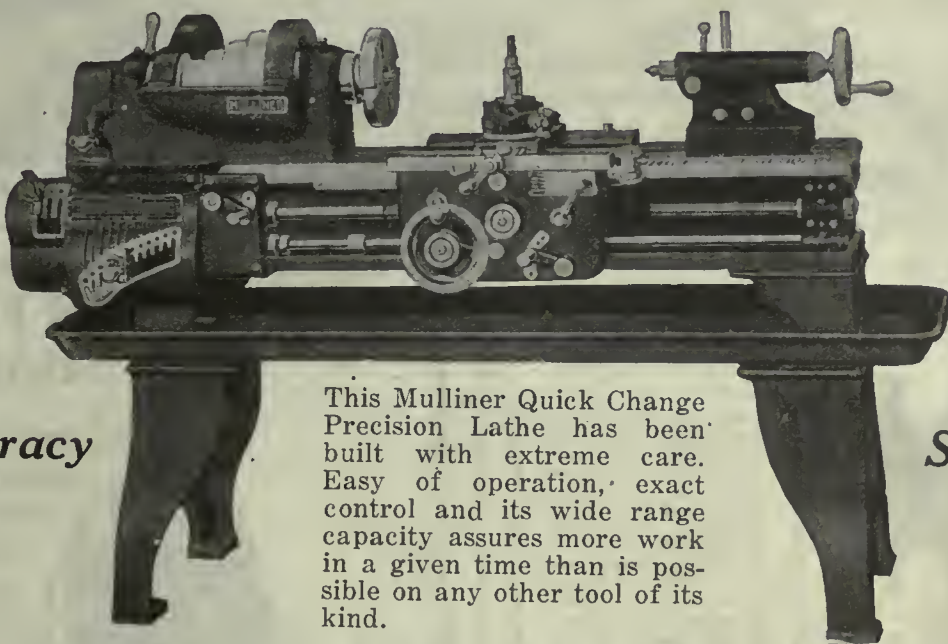
MULLINER

The Quick Change Lathe with 37 Different Threads and Feeds



Accuracy

Speed

This Mulliner Quick Change Precision Lathe has been built with extreme care. Easy of operation, exact control and its wide range capacity assures more work in a given time than is possible on any other tool of its kind.

Special features have been incorporated into Mulliner Quick Change Lathes which permit an absolute guarantee of accuracy to within .001" in boring and turning, and quick change mechanism provides 37 different threads and speeds.

The specially designed tumbler gears insure absolute minimum of wear, there being no clashing, when the gears engage. This allows for greater speed. The absolute lack of all superfluous mechanism is another feature that promotes speed. Sizes 12" to 14" with 4", 5" or 6" bed.

Mulliner-Enlund Tools are built for speed, for accuracy, for economy in operation. Pleased to tell you more about them.

Load---Unload---Convey---or Stack---at ½ Your Present Cost

Four things explain why the Brown Portable Handling Machines can save you from 50 to

75 per cent. over your present cost of handling your boxed, packed or rolled materials—because these machines are "built to fit the job," to fit every peculiarity of your handling conditions, because their carrying motion is continuous and because they are portable and sectional. You roll these machines to wherever the job is. If conveying, and you have a long stretch, you add so many sections. If a shorter stretch, you take out so many sections. Every machine carries its power with it—either electric, gasoline or kerosene.

Portable Continuous Motion Elevators — used to stack or elevate, or to load trucks, or used as a portable floor-to-floor Elevator;

Portable Continuous Motion Sectional Conveyors to eliminate all truckers and trucking between loading and delivery points; Portable Continuous Motion Loaders-Unloaders to load or unload cars, boats, according to design. Each machine may be used as an independent unit or as one of a series when any two or three handling operations may be performed as *one continuous* motion handling movement. Motion reversible. Made to handle barrels, boxes, kegs, drums, rolls, bags, coils, etc.—any package. Used in warehouses, mills, industrial plants, by steamship and railroad companies, by municipalities, by the United States, the British, French, and the Russian Governments — in use in 35 different countries because they save money and time.

Send complete details for suggestions on most economical handling methods, asking for Bulletin No. 141.

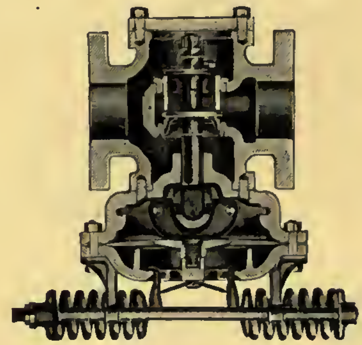
Auxiliary Operated

Angle Body Straight Body
Quick. Sensitive. Does not leak.

Wherever water or other liquid is used and the tank is of large capacity, or is located at a high point, it becomes an economical necessity to hold this level with a minimum of waste. The Foster Float Valve is the most satisfactory device on the market for this work.



Class "W"

The Foster Pressure Regulator

Over 75,000 in Use

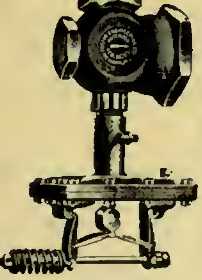
FEATURES

A compensating spring movement, exerting an unvarying pressure on the diaphragm.
Renewable seat rings.
Drop forge stem, levers, toggle levers (case hardened) insuring durability.
Great simplicity of construction and operation.
Small movement of diaphragm, insuring long life.
Ample steam capacity.
No friction of parts.
No small parts to clog.
No dash pot.
Noiseless in operation.
Absolutely automatic after adjustment as to pressure.
Every regulator carefully tested before leaving factory.
These regulators may also be applied on service other than steam. The manufacturers will advise if desired.

The Foster Class "G" Pressure Regulator

A superior, high grade pressure regulator that positively regulates.
Does not leak. Does not stick. Never fails.
Designed for severe and exacting service requiring close regulations, particularly for intermittent work. Suitable for working pressures up to 250 pounds. Main adjusting spring and single diaphragm obtain practically unlimited range of pressure on the terminal side from zero to within a small percentage of the initial pressure. Also particularly adapted for air service where valve is required to shut off and hold tight. It will operate equally well on horizontal or vertical type, either upright, inverted or inclined at any angle.

Foster Class "Q" Pressure Regulator



For steam heating or other service where the delivery pressure does not exceed fifteen pounds.

It is not intended to take the place of our class "W," but to meet the demand for a somewhat lower-priced valve, in service where it will do the work as well as a more expensively constructed one. It includes some of the best features of the class "W"—among others the toggle device to compensate for the variable spring power.

Write CANADIAN FAIRBANKS-MORSE COMPANY for descriptive circulars and full particulars of any line in which you are interested.

The Foster Class "G" Pump Governor

FOR STEAM PUMPS OR AIR COMPRESSORS

It will, beyond question, give better results in active service than any other governor for the purpose known.

We recommend it for hard service where the most service and acting duty and close regulation is required. Auxiliary operated—gives full area through the valve with one pound (1 lb.) or less reduction may be applied at any point at any angle on the pipe line—a desirable feature where headroom is limited.

In these days of gigantic demand Nortons everywhere keep production up

Here's a grinding job up in Vermont at the Jones & Lamson plant. It's a Drum Drive Shaft for a J & L Turret Machine. The material is machine steel and its rough size is 1 9/32-in. x 1 17/32-in. x 1 25/32 in. x 1 13/32 in. The finished size is 1¼ in. x 1½ in. x 1¾ in. x 1⅜ in.

A limit is set of .0005 in.—and maintained at the rate of 28 complete shafts per day.

Isn't an installation—in a plant so thoroughly well known in the quality field as Jones & Lamson—an endorsement for Nortons that you can't afford to overlook when you are ready for grinding machines?

Place cutter on table, lower spindle until nose enters cutter, fasten with drawing-in bolt—

Simple, isn't it?

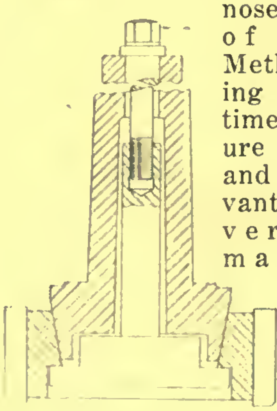
And it is just as simple as it sounds to put a face milling cutter of any size on

Brown & Sharpe Vertical Spindle Milling Machines

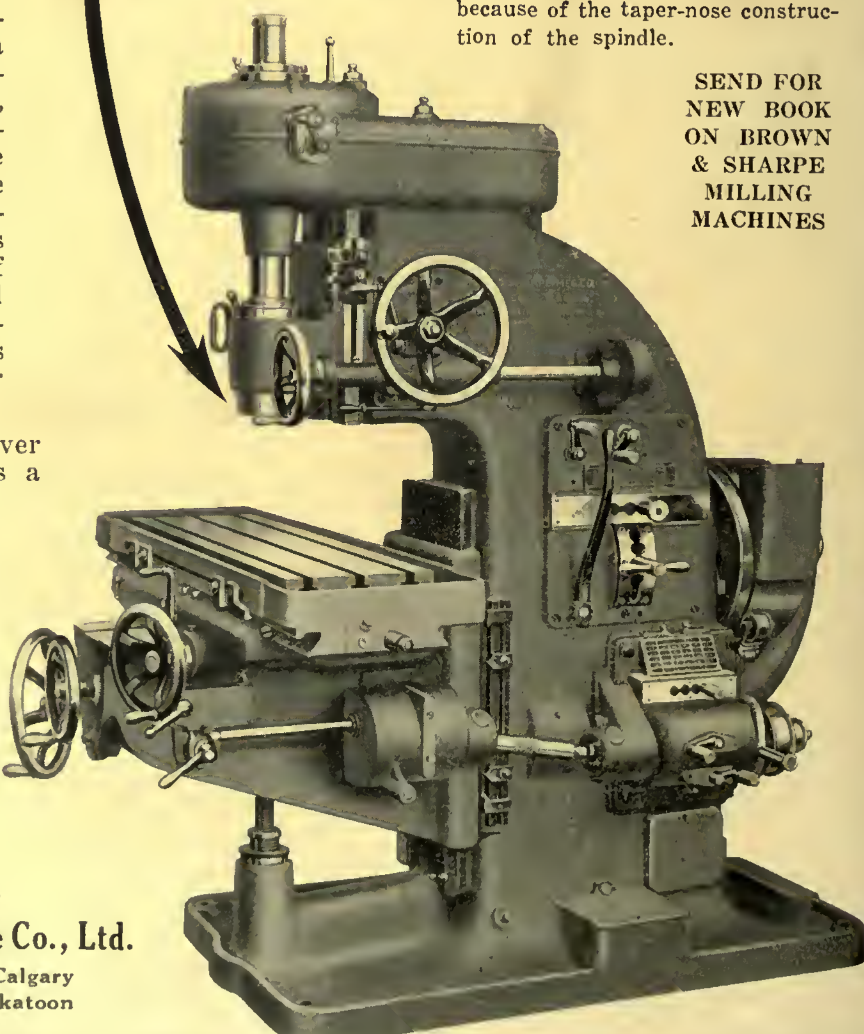
because of the taper-nose construction of the spindle.

SEND FOR NEW BOOK ON BROWN & SHARPE MILLING MACHINES

Only a drawing-in bolt and cutter driver required to hold and drive face milling cutters on Brown & Sharpe Milling Machines because of the taper-nose construction of the spindle. Method of attaching cutter is a time-saving feature on all types, and especially advantageous on the vertical spindle machines. Diagram shows method of holding and driving cutter by means of cutter driver and drawing-in bolt.



When in place the cutter driver serves as a clutch and assures a positive drive.



Let us tell you in detail of this and the many other features of

Brown & Sharpe Milling Machines.

Sleeve Bar with Holder.

Plain Bar

Williams' "Agrippa" Boring Tool Holders for Multiple Bars

RAISE NO BAR AGAINST THE SELECTION OF BARS
THE CHOICE IS YOURS

THE same holder can be used for all sizes of Boring-Bars which come within the range of either of the V grooves at top and bottom of the reversible Cap with the "twin-screw" fastening; no bushings or shims are necessary.

For instance, the smallest Holder, No. 080, accommodates Bars from 3/16 to 1/2" diameter, while the largest, No. 83, holds Bars from ½ to 1⅛" diameter. Three intermediate sizes of Holders are also in stock.

We furnish two types of Standard Bars as illustrated—they are interchangeable in the Holder.

In the *Sleeve-Bar*, the Cap admits a straight or angular Cutter; either can be quickly inserted at the business end of the Bar without removing the Cap or disturbing the setting of either the Bar or the Holder.

The *Plain-Bar* provides for the use of both styles of Cutters in the simplest manner possible and is furnished with Headless Screws.

"An Instant Fit"

Nicholson
EXPANDING MANDRELS

With Nicholson Expanding Mandrels there is no hunting through a pile of solid mandrels for a mandrel to suit the size of work.

One set of nine Nicholson Expanding Mandrels are all that's needed to fit any size square or round hole between one to seven inches.

They center immediately—and can be collapsed and knocked out in a few seconds.

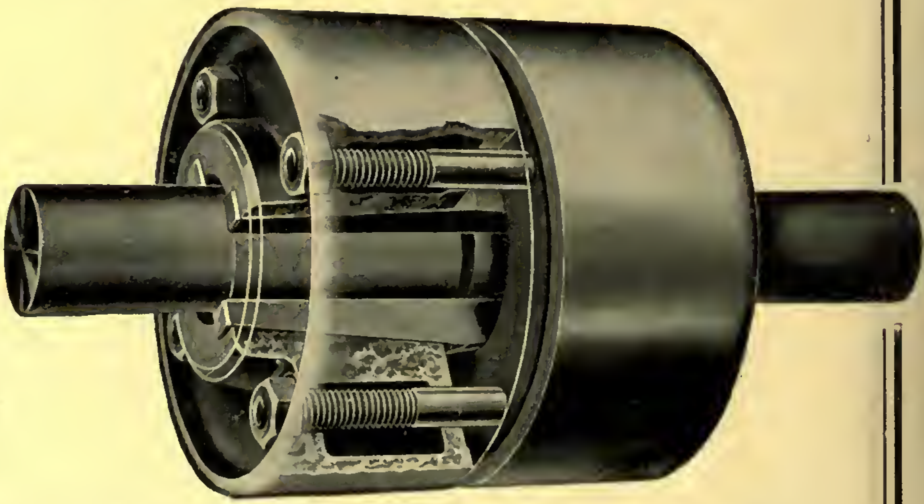
Make Every Move Count

Your machines will be producing every minute. Increased production simply has to follow, with greater accuracy.

"Nicholson" cannot distort. The jaws are always concentric.

Write us to-day for full details, or we will loan you one for thirty days. After that it is up to you.

Nicholson
PATENT
Compression SHAFT COUPLING



Severe working and dynamometer tests have proven that the Nicholson Coupling possesses the most powerful grip of any coupling on the market.

It is the only compression coupling known that will withstand a strain on a 5-inch shaft, that is sufficient to twist off the shaft itself, as the "Nicholson" has been known to do and in many cases on shafts less than 5 inches.

The reason why the "Nicholson" will twist off a shaft where its competitors will slip, is because it possesses a powerful **four-sided grip** (similar to that of a lathe chuck), obtained by drawing together the tapering bore castings over four double tapering steel jaws, secured by an ample number of through bolts; a grip that is unquestionably the most powerful that is obtainable.

The grip of the "Nicholson" differs from the other makes of couplings, most of which are constructed with a case split bushing—which compresses eccentric fashion, and does not conform to the shaft. In this style coupling there is a lot of power expended in overcoming the friction between the outside of the bushing and the bore of the flange castings.

The Nicholson coupling draws tight much easier than any other; as the friction is largely eliminated, and the four steel jaws make a perfect fit and grip.

OVER 50,000 NICHOLSON PATENT SHAFT COUPLINGS NOW RUNNING.

Drop us a line for full particulars.

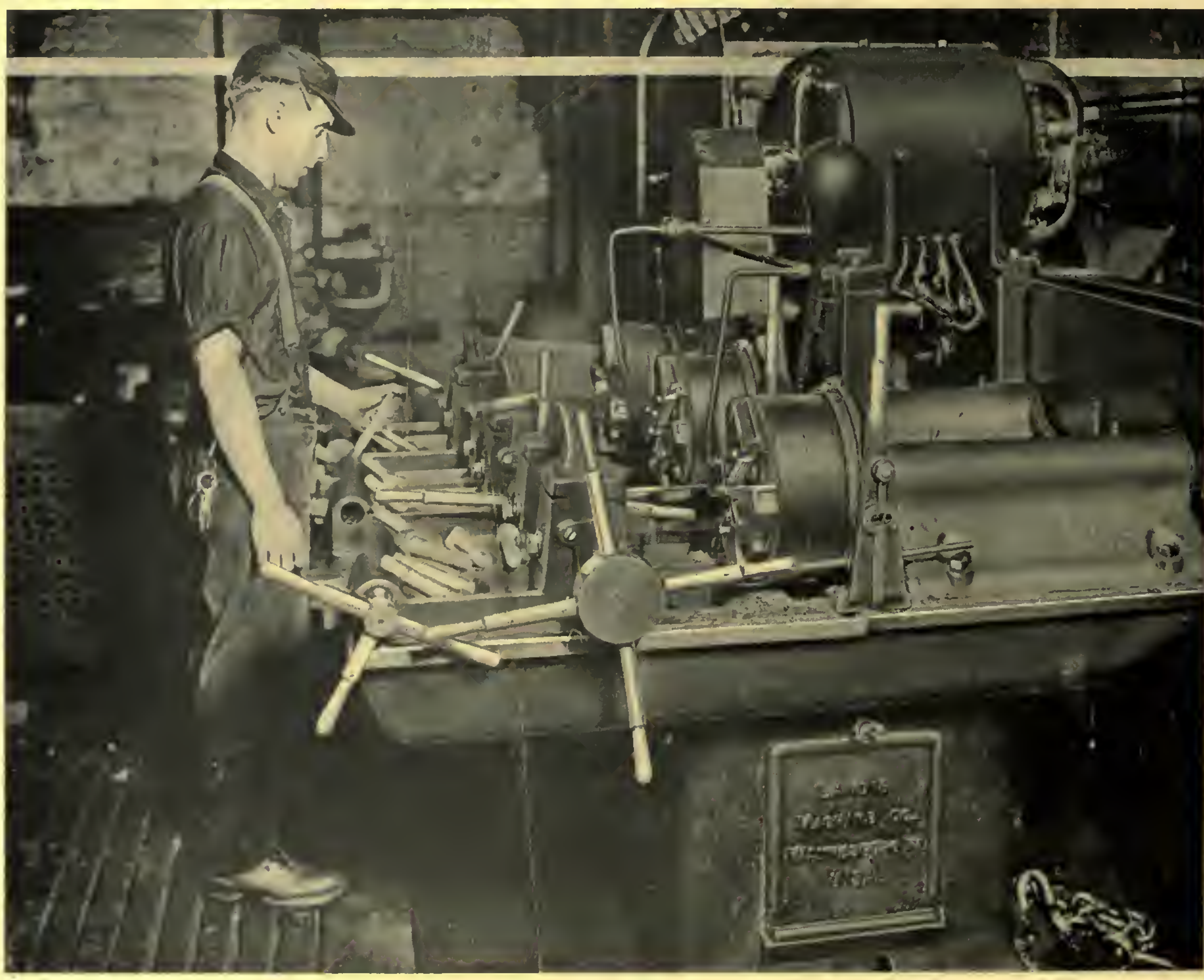
"No Trouble Since We Got This Threader"



Said the operator of this 2" Landis Triple Head Threading Machine, and he further opined that it could not be beaten for ease of operation and high production. This statement, made after eight years of service in a railroad shop, speaks for itself.

On an average, three thousand 1½" bolts are threaded every ten hours on this machine, but it is particularly advantageous for cutting long lengths of threads. The quality of threads is up to the Landis Standard, which means well-formed and accurate.

It was with a machine similar to this one that a test was made in a big railroad shop as to the economy of Landis Dies as compared with other types. It was found that when the Landis Die was used it cost $4.95 to thread 100,000 bolts, and with the other types of dies the cost was $48.39. Needless to say the Landis Die, by cutting costs to almost one-tenth was adopted throughout the plant.
How much does it cost to cut your threads? Submit your specifications and we will show you the Landis way.

WALCOTT SHAPERS

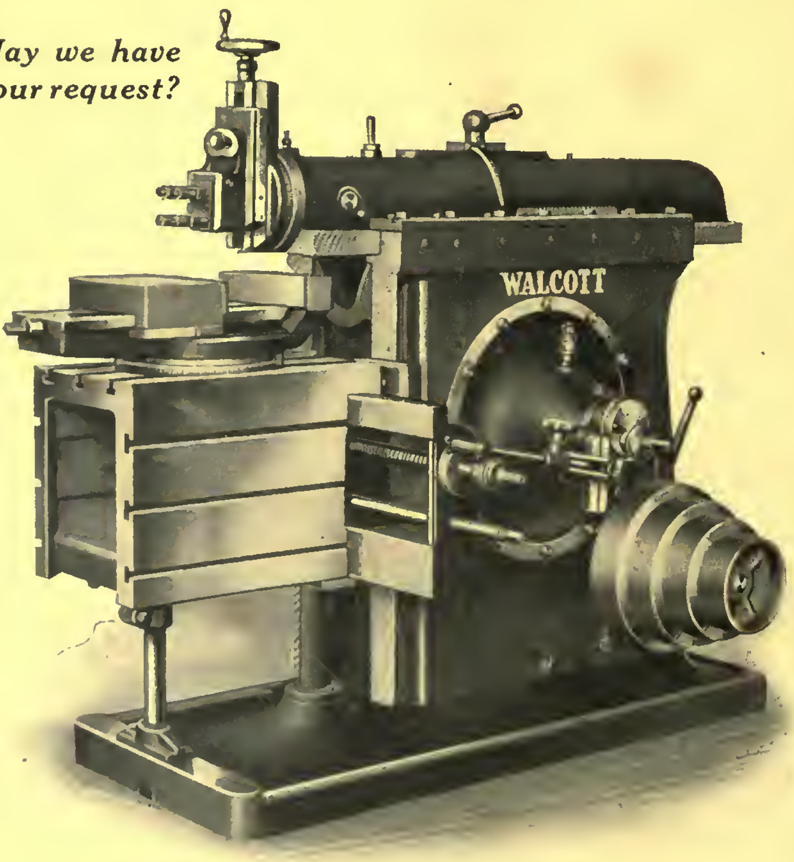
Built to Endure—

Walcott Shapers are built to endure the hardships imposed upon shop equipment during the war-time pressure of heavy production. Prominent features in this connection are the general heavy construction where strains are most likely to occur, extra large bearings throughout to compensate for wear, and perfect lubrication.

The bull gear pinion is made of high carbon steel, and runs loose on the ground shaft of high carbon steel. Bronze bushings are provided in this pinion, and the same is oiled by a large oil chamber through the centre of the shaft.

All gears are of coarse pitch and wide face and helical design, thus insuring a quiet, smooth running machine with absence of any chatter. This permits a greater number of cutting strokes, thereby increasing the output of the machine.

May we have your request?



The above are but a few of the good features that are responsible for the great endurance qualities of the Walcott Shaper. We have not touched on the features of simplicity, ease of operation, high speed features, etc., but we would like to send you bulletins giving all the details of our shapers.

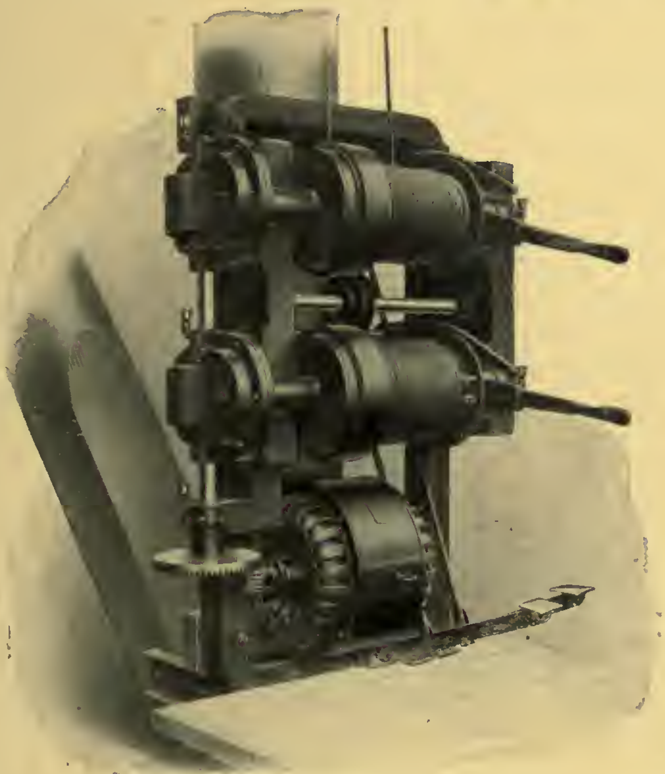
ELECTRIC HOISTS



This is a new design of hoist made in two sizes with capacities of 1,000 lbs. and 2,000 lbs. on a single line. These machines are designed with high speeds for fast work on light loads. Loads of 5 tons on the smaller and 10 tons on the larger can be handled with proper arrangement of hoisting lines.

This machine is self-contained, main reduction is through steel worm and bronze worm wheel running encased in grease. Load is picked up by large cone frictions, lowered by hand break, and held automatically by forged steel dog. Constant speed standard motors used. Machine arranged for vertical or horizontal position as required.

Single I-Beam and Double I-Beam Cranes

Capacities 1 to 10 tons, spans 15 to 40 ft. Truck wheels have chilled treads, roller bearings. Trolley wheels have turned treads, roller bearings. Clearance required 4" from center of rail to outside, minimum head clearance.

JIB CRANES. Electric Jib Cranes 2 to 5 tons capacity. We have designed and manufactured two of the largest electric jib cranes in use, 5 tons capacity, 60 ft. boom, 60 ft. mast. High speeds, 60 ft. hoist, 250 ft. trolley travel, ¾ turn in 15 seconds.

DERRICKS. Large steel derricks, both stiff leg and guy type. Capacities from 10 to 50 tons. Derrick irons for wooden derricks, 10 to 25 tons capacity.

A Better Belting

—because it is better built

OUR own practical experience with Goodyear Extra Power is one of the best reasons we have for recommending its use to you.

We have used this modern type of belting in our own plant—used it largely, on all kinds of drives.

We have found it a better belt—a belt that yields splendid service — long and trouble-free service — under the most difficult conditions.

That's because it is scientifically constructed to ensure those features you expect from a belt—lasting service, economy, flexibility, freedom from trouble.

Its construction guarantees great strength and balance, without power-squandering weight.

"Extra Power" is flexible—it is long-lasting.

Add to its natural flexibility its gripping surface and you have a belt that hugs the pulleys for the last ounce of power.

No obligation is involved in getting the trained and expert advice of our belting men.

METLSKIN does prevent scale

Send for this illustrated booklet. It explains the dose, the method of action, and other important details

Some of Canada's and the United States' biggest and most representative plants have learned the truth of the above statement from first-hand experience.

So many "compounds" and "cure-alls" have been foisted upon unwary power-plant owners that the feeling, common to many of them, is one of doubt, of skepticism. And small wonder!

METLSKIN is not a "compound," nor does it work on the same principle. It is a boiler metal treatment, a boiler preservative that gradually removes scale by a safe process.

When the scale has been entirely removed METLSKIN forms a minute, grayish-white skin or covering over the bare metal.

So long as the daily dose is continued the scale-forming particles in the feed-water cannot adhere to the metal. Nor will METLSKIN work injury to any part of the boiler or system. That is one of the strongest features of the GUARANTEE BOND.

METLSKIN cannot contaminate the steam. It may be used safely in any plant where live steam comes in contact with the manufactured product.

If you are a skeptic, a doubter, ask for the booklet, GUARANTEE BOND, prices, etc. You will be interested, we know.

This Tool

was tested in a well-known plant in New York

It is a Davidsonized milling cutter, 4" diameter by ½" face. Run at a speed of 250 R.P.M., and with a feed of 7" per minute, taking a cut ½" wide by ½" deep, it worked without any difficulty for ONE HOUR AND THIRTY-TWO MINUTES.

As against this, a high-speed steel milling cutter of one of the best-known makes, and also a cutter made from one of the best-known high-speed steels, ran under the same conditions for TWENTY-EIGHT MINUTES. At the completion of the test the Davidsonized cutter was in better condition than either of the other two tools.

The material tested was .45% Carbon Open Hearth Steel, containing .70% Manganese.

*Name on request.

You Can't Get Away From Facts Like These

We claim that it is possible in a majority of instances to obtain similar results.

Davidsonized High Speed Steel

offers you great opportunities for increased production, long service and tool-making economy. We guarantee any tool of Davidsonized High Speed Steel to give you at least 10% better service than any other tool you have been using on corresponding work. You will be the sole judge. More and more of the leading machine shops are turning to this steel of remarkable service, because—

(1) It increases production 10% or more. Such an increase, figuring factory overhead and labor, multiplies several times over the value of the tool.

(2) The guarantee above gives absolute protection.

(3) Davidson Special Service cuts tool-making time and tool-room costs.

SPECIAL SERVICE

We will supply Davidsonized Tools, semi-finished and easier to machine than any carbon tool steel, within approximately 1/64 of finish on face, 1/64 in bore and 1/32 in diameter, leaving only the final hardening and sharpening to be done in your tool room. A tool that takes 20 hours to make from the solid bar can easily be finished from a Davidsonized blank in about two hours. And we will guarantee our tools against breakage in hardening.

This service, though it applies also to standard tools, is especially desirable in the case of tools made to unusual shapes and other specifications.

Use this special service. It costs you less than to bring your tools from the bar to the stage at which we furnish them. It eliminates the loss by breakage in hardening. And, most important of all, it gives you better tools than you have been using, tools capable of such performances as the one described above, tools that will boost your production and give you longer service. Send us a trial order; our guarantee prevents all risk. Correspondence invited.

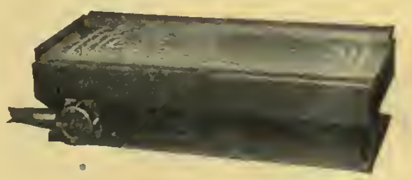
"D & W"
Magnetic Chucks

Heat-proof - Oil-proof - Waterproof

"D. & W." Magnetic Chucks are designed to secure the maximum effective holding surface, with exceptionally strong and uniform pull throughout, whereby a wider range of work can be machined than was formerly practicable.

The magnet coils in "D. & W." Chucks are wound and insulated by a special process which protects them from heat and moisture.

All chucks are equipped with special enclosed type demagnetizing switches, for automatically releasing the work.



We also manufacture a complete line of specialties, including taper, swivelling chucks, and A.C. and D.C. Demagnetizers. Prices quoted upon application.

"D. & W." standard flat and rotary chucks are designed for use on either 105-125 volt or 210-250 volt D.C. circuits, but not on both ranges. In ordering chucks specify voltage of lighting circuit. Alternating current cannot be used.

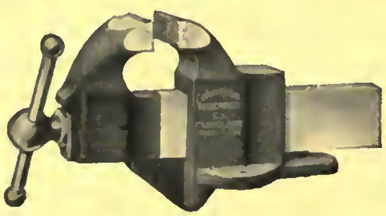
COLUMBIAN

Sledge-Tested VISES



All Good Points In One Vise

NO matter what other make of vise you favor you'll find its best features in Columbian Sledge-Tested Vises — and in addition, many good points of its own.

Some men select a vise for deep jaws. Others want a vise with removable steel jaw facings. Still others attach most importance to simple, quick-acting adjustment of jaws or swivel base.

Columbian Sledge-Tested Vises will give you all of these and in addition an unbreakable vise. Columbian is the only hollow-jawed malleable iron vise made. You can hammer it with a 16-pound sledge and not break it. It is twice as strong as a cast iron vise and you can obtain a Columbian Vise in any style or size you want at the same price you'd pay for an old-style vise.

The makers of Columbian Sledge-Tested Vises are the largest makers of vises in the world. A thousand jobbers and mill supply houses sell Columbian Vises.

Just What You Need For Grinding Your Hardened Tools

Mechanics everywhere specify the DUMORE when buying grinding equipment because of the tool's reputation for service and satisfaction. It easily handles all kinds of work—longitudinal, cylindrical or internal.

Because each armature is dynamically balanced, the high speeds of the DUMORE, ranging from 10,000 to 50,000 R.P.M., are found not only practical, but indispensable to correct cutting speeds for small emery wheels. Jobs are consequently free from danger from chatter, taper or bell mouth.

Let us demonstrate what a big saving you can realize with a DUMORE grinder in your shops.

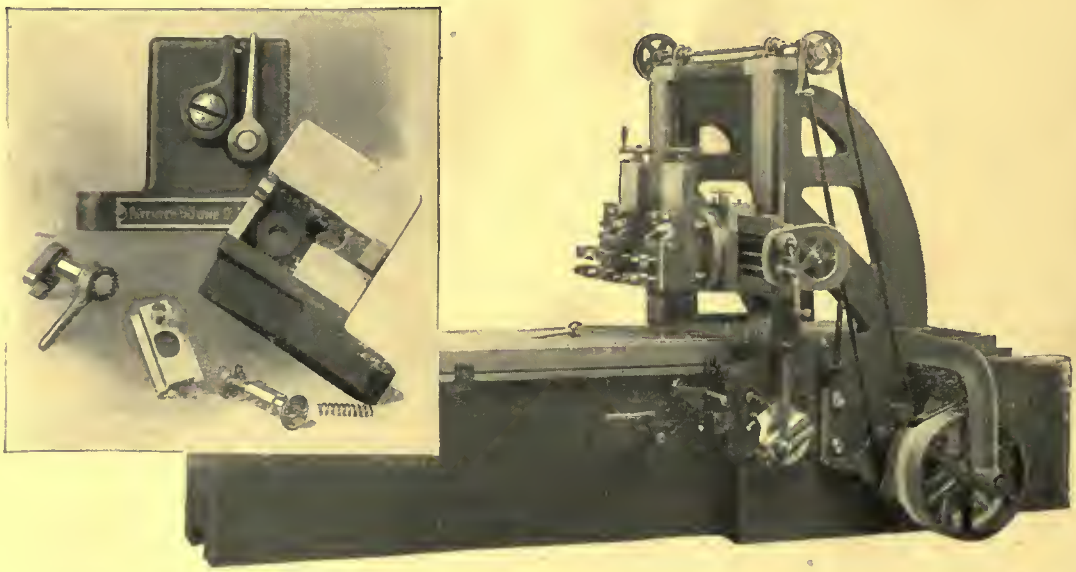
Distinctive Features that Build Speed Into Whitcomb-Blaisdell Planers



The Patented Self-Locking Shipper Dogs

Provide Quick and Easy, Yet Safe Adjustment of Table Travel.

Finger pressure upon the small lever releases the shipper dog for shifting. When slid into the desired position, the releasing of the lever locks it instantly and automatically.

No wrenches are required for adjusting these shipper dogs. No time is wasted; only a moment is required for positioning the table travel just as required by the work.

The danger of the operator being caught between the table and the housing of planer, while changing the stroke, is entirely eliminated.

This is typical of the many provisions for rapid adjustments on the Whitcomb-Blaisdell Planer.

It is not alone the extremely high cutting speeds, permitted by the Patented Second-belt Drive, which makes the Whitcomb-Blaisdell Planer so productive. Hardly less important a factor is the completeness of its provisions for speed in adjusting and operating.

Write for our latest Catalog, which tells in detail all the reasons for Whitcomb-Blaisdell Planer Speed.

THE WALCOTT LATHE

Promises or Actual Performances?

A new product may survive for a time on promises for the future, but an old one can only justify itself on records already achieved.

For the past 38 years Walcott Lathes have proved their ability in **actual service.** In the present emergency they have risen to the occasion, and for a production Lathe, they have a remarkable speed and accuracy.

Walcott Lathes have a compound rest which has no overhand, and is as stiff as any plain rest. A quick-change gear box, unusually wide bearing surfaces on the bed, exceptionally wide bridge to carriage, and many other features we have added during the 38 years Walcott Lathes have been on the market.

Made in 14", 16", 18", 20", 26" and 29" sizes.

Write for full details.

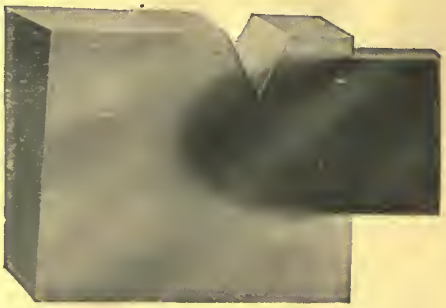
Plain Bearing Induction Motors *Ball Bearing*



A cut section of End Ring and Bar showing the perfect joint.

Sturdy Construction—Efficient Operation

No Joints in the Rotor—the end rings are *cast* in place. We recommend particularly the Ball Bearing Motors. They save money. They are efficient and clean. They require only occasional lubricating with grease. The motor may be mounted on wall or ceiling without changing the motor frame—The Ball Bearings have no distinct top and bottom.

Put a Belt as Good as this on *Your* Pay-roll

This Graton & Knight 40" 3-ply Heart Brand Belt is five years old. It is running every day on heavy duty for the Milford Light and Power Co., Milford, N.H. The cost of this belt in cash has been $1.81 a week, or .004 per delivered horse-power per week.

Put a belt as good as this on your pay-roll. Its low cost of upkeep is the result of Graton & Knight Standardization. That means the proper belt for any given requirement. It means the right quality of leather and the right kind of tanning for a given purpose. It means true economy—full delivery of power, without waste.

Leather is the ideal belting material. It has a characteristic pulley-gripping quality. It has pliability with light weight. It has the stretch and the come-back that gives and takes. It stands mauling by shifters and the gruelling strain of main drives. It is firm and strong. It is tough, but tractable. These are the characteristics that good belting must possess.

Every year nearly 300,000 hides are tanned in the G. & K. factory. That gives uniformity. The more stock handled, the more latitude there is for picking equal-quality material for a given specification. And G. & K. Tanning is of a fixed standard of quality for specific requirements. We make all kinds of leather belting, for every use—large and small.

Load carried and conditions of operation must figure largely in the length of service of any belt. Some drives limit belting to a few months or even a few weeks. Graton & Knight Standardized Series Belts are made to give the longest possible delivery of efficient power at the lowest possible cost. And they do it. It may be that belts all look alike to you—and it may be that you are spending more than is necessary for some belting requirements. We can and will help you find out.

Many of the best-belted plants ask us to specify the belting for every drive. Try the plan yourself. Then, when buying, call for "Graton & Knight——Brand or equal" This won't commit you to buying our belts. It will put your buying on the one basic consideration—the work to be done.

Supporting the Line of Industry

The industrial problem of the day is how to save power and conserve the diminishing fuel supply. Transmission losses due to friction of plain bearings amount to from 20% to 40% of the total power used in the plant.

SKF Ball Bearing Hangers will reduce these losses over 33%. This saying alone will make their installation a profitable investment. Then, too, the lubricant savings and the impossibility of hot bearings is an item to consider.

We have a special catalog describing their use in your line of business. Send for a copy.

Where You Find A
GISHOLT
Tool Grinder
You'll Find Properly Ground Tools

And where you find properly ground tools at the machines, ready for use the instant they are needed, you will find all machines busy, as the operators do not have to leave their machines standing idle while they go to sharpen their tools.

The Gisholt Tool Grinder is more than a grinding machine. The direct benefits are far reaching.

Let us tell you the complete story and show you what this machine has done for some of its purchasers.

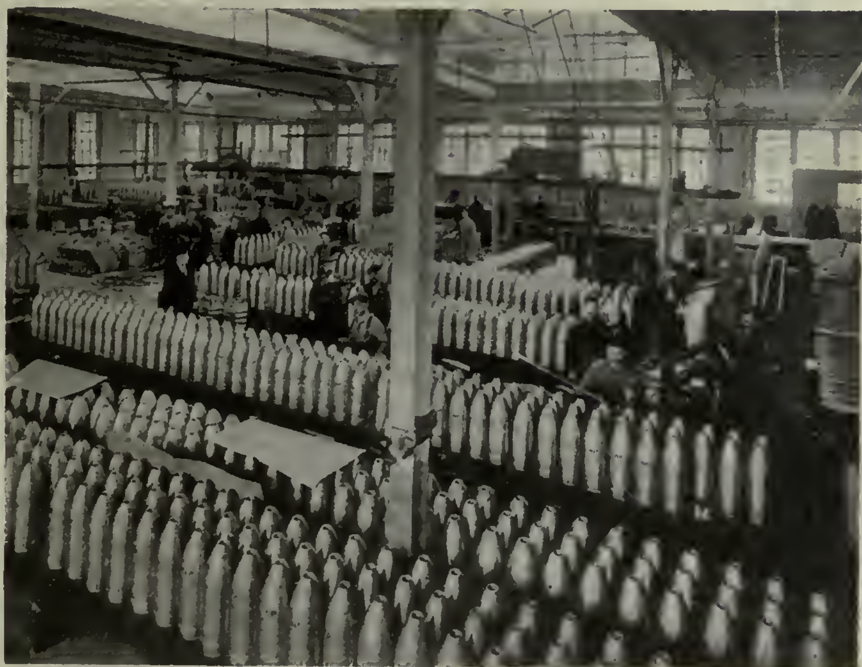
Volume XX. No. 26. December 26, 1918



CANADA MADE A REMARKABLE RECORD IN PRODUCTION OF MUNITIONS

Canadians Undertook Work of Mastering New Industry and Succeeded

By T. M. FRASER, Ottawa Representative MacLean Papers

OTTAWA, December 26.—Among the romances of commerce which the war has produced in Canada, there is none more striking than the organization and work of the Imperial Munitions Board, which, in the three years of its operation, furnished to the Ministry of Munitions and other departments of the British Government, Canadian manufactures to the value of one billion, one hundred million dollars. This enormous commerce was developed literally from the ground up, because, prior to the beginning of this war, there was no munitions industry in Canada, or no thought that such an industry was capable of any serious development. Mr. Churchill might well say, as he took the earliest opportunity to do in a handsome acknowledgment of the work of the Munitions Board on the cessation of hostilities, that "Canada's remarkable output of munitions has played a large part in the munitioning of the British armies, and will remain a testimony to the high value of the work of the Board in this great struggle"; a tribute in which Premier Lloyd George coupled the staff of the Board, the Canadian manufacturers, and the great army of workers who so splendidly assisted.

As a matter of record, it might be noted that the first shells made in Canada and shipped from a Canadian plant, outside of a few at the Quebec arsenal, were made at the C.P.R. shops at Montreal, and this was mainly due to the keen personal interest taken in the matter by Lord Shaughnessy. The British army tried them and pronounced them good. Then small orders began to come in from Great Britain, and the manufacturers got interested. Gradually orders came for the larger shells. No order, great or small, was ever turned down.

The second plant to take up the work was the Ingersoll-Rand Drill Company at Sherbrooke. Although no Canadian manufacturer had ever previously made a shell, or a cartridge case, or a fuse, they were willing to try. In December, 1914, there were two firms shipping; January, 1915, 8 firms; April, 1915, 14, and in June, 1915, 36 firms, with an average weekly production of 77,000 shells. The maximum point in the industry was reached in June. 1917, when 53 firms were engaged in the work, with an average weekly production of 386,000 shells.

A few 13 and 15 pound shells were made at first, but serious production was early directed to the 18-pound shrapnel. In fact, while the industry was handled by the Shell Committee, which it was for the first fourteen months, it was mainly engaged in the production of 18-pounders and high-explosive. Cartridge cases and some other component parts were also produced in small quantities, but no complete rounds.

Working Under Adverse Conditions

The Shell Committee had done good work. It broke the ground, and was instrumental in inducing Canadian manufacturers to engage in the new industry, which many of them were loath to do. In the criticisms which were so freely made of both the Committee and the manufacturers, little thought was given to the conditions under which they were operating. To engage in the work meant practical abandonment of the plant and organization which they had built up, to engage in a work which was unknown to them, and to embark their capital in an industry, the life and death of which was uncertain. This was a time, it should be remembered, when men were predicting an early end to the war. Under such conditions no one would be likely to engage on what all admitted was a very necessary work except at a rate of profit higher than normal.

Criticism was not lacking. It was painful and frequent and free in public, press, Parliament, and even in the pulpit. The result was that the existing arrangement became unsatisfactory to all concerned. The Shell Committee went out of business after having been responsible for about 3,800,000 shells, and its place was taken by the Imperial Munitions Board.

Turned to a Real Autocracy

The organization of the Shell Committee had been democratic, and like many of the creations of democracy, it had failed to give satisfaction to its creators. The Imperial Munitions Board was a pure autocracy. Final authority and responsibility was vested in the chairman, Sir Joseph Flavelle, the other members of the Board being: Brigadier-General Sir Alexander Bertram, vice-chairman; R. H. Brand, representative of the Board at the Ministry of Munitions, London; Col. D. Carnegie, ordnance adviser; G. H. Dawson, Brigadier-General W. E. Edwards, R.A., director of inspection (Canada); F. Perry, financial member; J. A. Vaillancourt; E. R. Wood. Sir Charles Gordon was representative of the Ministry of Munitions in Washington. The Board was an integral part of the British Ministry of Munitions, directly responsible to the Minister, and the British Government was financially responsible for all its expenditure, although the Government and the banks of Canada advanced three-fifths of the total sum expended.

The Imperial Munitions Board took over the work in November, 1915, when the demand for shells was still small in comparison with what it soon became. The development of the systems of barrage and intensive bombardment created a new problem for the munition makers, creating a demand for shells never hitherto dreamed of as possible. Canada was asked for six, eight, and nine inch high-explosives, and also for the component parts to produce complete rounds, and the Ministry of Munitions seemed to have a considerable degree of confidence that it would get them. It was waking up to the possibilities of Canada as a source of supply, and the Canadian manufacturers were waking up to their own ability.

The Work of Organization

All this meant something very much more intricate and elaborate than any problems which the Board had hitherto encountered. It was seen that the work must be allocated among the forty or more firms which had by this time gons into munition making, and that provision must be made for controlling their supply of raw materials and machinery as well. The motto of the Board became: "From each one according to his ability; to each one according to his needs." This was good for both the Government and the manufacturers; it regulated supplies and stabilized prices both of raw material and of the finished product.

A purchasing department was organized to supply the manufacturers with their raw materials; a distribution department which directed the supply of the same to the best advantage, and a production department which had supervision of manufacture, and rendered expert advice and any other assistance required. There was also a labor department for the supply of help to the plants, and an inspection department who work was of the most vital importance and assistance, not only to the Government, but to the manufacturers as well. The inspection department had as many as eight thousand persons on its pay roll.

The organization of the Board was well-nigh perfect. It summoned to its assistance, in one capacity or another, the best brains and skill available, and it worked in the utmost harmony. It may be imagined that any organization having in its hands an expenditure of over a billion dollars early attracted the notice of the birds of prey. Graft, like death, loves a shining mark, but the men at the head of it were determined that the British taxpayer, who was paying a fair price for what he was buying, should receive full value for every cent of that billion dollars, and it was not long before the fact was fully understood that the Board was not a mark for anyone. After that it was left severely alone by all except legitimate business men, and they have always been glad to do business with it.

Newspapermen may, perhaps, have a slight grudge against the Board. It was almost barren of information. It did not seek publicity; in fact its business was of a kind where the utmost secrecy as to its operations had to be maintained. It is notable that in all the time its mommoth operations were being conducted there was never a "leak" of any kind. All that was being known was that the Board was producing the goods not only to the satisfaction of the Ministry of Munitions, but to its surprise and delight.

Went Into All Phases of Work

The mere manufacture of shrapnel shell was an accomplishment in itself, but it was slight in comparison with the work involved in furnishing the complete munitions. This meant buying steel, copper zinc, lead and antimony. The steel had to be rolled into bars, the bars forged into shells, and the forgings machined. The copper and zinc had to be made into brass, the brass into discs, and the discs into cartridge cases. The lead and antimony became bullets. and the bullets produced "good" Germans. Explosives had to be made or bought and filled into shells, fuses, or cartridge cases.

Existing plants could not cope with the Board's demands, so it built plants of its own—enormous plants. The fuse plant at Verdun; the British Forgings at Toronto; the explosives plants at Renfrew, Nobel and Trenton; the aeroplane plant at Toronto—when you examine the perspective drawings of them on the walls of the Munitions Board offices at Ottawa, you wonder at the energy and organizing ability which made these modern forges of Vulcan spring up overnight. If you were a German you would say: "An enemy hath done this thing, and you would have as much respect for the Canadians who were behind the man behind the guns as for those who aimed and fired them. Once, when Randolph Churchill tried to hold up a Government of which he was a member, he found his plans upset by reason of the fact, as he said, that he "forgot Goschen." One of the factors the Kaiser failed to take into account when he started to upset the world, was little one-horse Canada.

And this is not mere braggadocio, either. When Randolph Churchill's son cabled his congratulations the other day, he had in mind the fact that in the second half of 1917 Canada was producing 55 per cent. of the shrapnel, 42 per cent. of the 4.5, 27 per cent. of the 6 inch, 15 per cent. of the eight inch, and 16 per cent. of the 9.2 inch shells used by the British armies. Wilhelm remembered Canada then. In addition to the munitions for the British Government, the Board at different times was filling orders for the Italian, Russian, and Belgian Governments, and when the war was ended, was handling very large orders for the United States.

Conditions Better Than in States

One of the surprising features of the war has been the comparative failure of our neighbors in certain particulars wherein they have always been reputed to be notably strong, and the display of an unlooked for moral strength. The failure of the United States in the matter of munition and aeroplane production as compared with Canada's handling of the same problems, was as pronounced as their superiority over us in the matter of solving the conscription problem, or the handling of the I. W. W. and other revolutionary malcontents. The dislocation of the ammunition and aeroplane programme with our neighbors appears to have been largely due to a lack of co-ordination of the manufacturing end, a problem which, as already mentioned, was solved here very early by the Board, when it organized its purchasing, distribution, and production departments, and itself took in hand the centralizing of the supply of raw materials. It is a very fine thing that two good neighbors should be able and willing to learn from each other and profit by each other's successes and failures, and this we have both done.

The activities of the Board were not confined to the production of war materials. They showed such a willingness to take on new problems and handle them successfully that the British Ministry of Shipping asked for aid, and at the end of 1916 they had begun placing orders for steel ships and reviving the wooden shipbuilding industry in Canada. They placed orders for 215,000 deadweight tons of steel ships in all, and undertook the construction of 140,000 tons of wooden steamships. The wooden shipbuilding industry, in which Canada was once a leader, had fallen so low that it was confined to the construction, mainly, of small coasting and fishing ships on the Atlantic and Pacific coasts. In Eastern Canada the Board arranged for the building or expansion of eight yards, and on the Pacific it took over two yards and constructed four more. The impetus thus given to the industry has led to a wonderful expansion on both coasts, and while wooden ships may never come back permanently, they have filled a great need, and will probably continue to do so for some time to come.

When aeroplanes and aeroplane spruce became a crying need of the Allies, this "Handy Man" of the British Government was again ready to step into the breach. They have managed all the business and construction side of the Royal Air Force in Canada, which, when peace came was producing air fighters at the rate of between three and four thousand a year, as well as large numbers of machines to fly and fight in. The Allies wanted spruce, which is the best wood for aeroplanes, and Canada had lots of it. The Board sent one of its experts, Major Austin Taylor, to the Pacific Coast to assist the lumber producers in securing it, and it was not long before this problem was satisfactorily settled.

Here Are Some Huge Totals

We can't get away from figures where the Munitions Board is concerned. It has created a new standard for Canada in the way of big figures. It put us on the map as a billion dollar manufacturing concern. Here are some of the Board's records, approximately:

The following figures give a summary of Canada's accomplishments, during the last four years, in the production of munitions of war, referring especially to the British contracts:—

Total number of shells produced	65,000,000
Approximate number of components represented by above, for which Imperial Munitions Board has let separate contracts	800,000,000
In addition to the 60,000,000 of shells produced, there have been a great number of components exported, such as forgings, cartridge cases, primers, copper bands, time and graze fuses, exploder containers, friction tubes, etc. In the production of this war material steel has been used to the amount of, tons	1,800,000
(About 75% of this steel is Canadian product).	
Quantity of high-grade explosives and propellants produced, lbs.	100,000,000
Value of orders placed by the British Government through the Imperial Munitions Board	$1,200,000,000
Amount furnished by Imperial Government for above purpose from sources outside of Canada	$400,000,000
Amount loaned to the Imperial Government by the Government of Canada and by the Banks in Canada for purposes of the Imperial Munitions Board	$600,000,000
Approximate number of contractors in Canada amongst whom contracts for munitions have been distributed	1,000
Number of workers engaged in war contracts	200,000-300,000
Approximate number of persons employed in handling stores in transportation and other collateral organizations	50,000
Approximate total number of workers	350,000

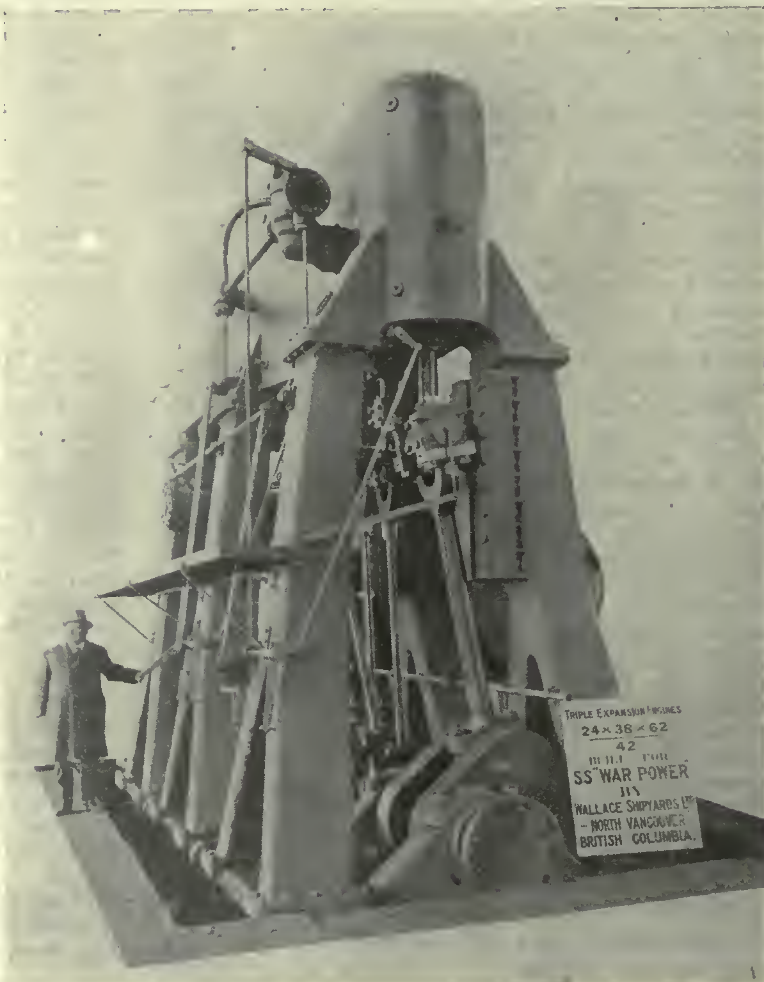
British Columbia's Part in Ship Programme

The Year Has Seen a Tremendous Revival of Industry in the Pacific Coast Province—What the Future Has in Store.

By A. F. MENZIES



DURING the past twelve months or so, British Columbia has, so to speak, come into her own as regards shipbuilding. The extensive program undertaken by the Imperial Munitions Board Wooden Shipbuilding Department has been completed, resulting in the addition of 27 wooden steamers of a total D. W. capacity of over 75,000 tons. Of steel boats 40,000 tons D.W. have been passed into service.

The Imperial Munitions Board wooden shipbuilding programme was carried out by yards which built the hulls only, the Imperial Munitions Board being responsible for the supplying and the installation of machinery, etc. The 27 hulls were divided up between the following concerns: Wm. Lyall Shipbuilding Co., Ltd., 6; Western Canada Shipyards Ltd., 6; Western-Genoa Co., Ltd., 4; The Foundation Co. of Victoria, Ltd., 5; New Westminster Construction and Engineering Co., Ltd, 4; Coquitlam Shipbuilding Co., Ltd., 2.

The boats are of the well decked type with the poop extended to the bridge deck. They are 250 feet long B.P., by 42 ft. x 6-in. mld. beam, by 25 ft. mld. depth. The carrying capacity on a draught of 21 ft .is about 2,800 tons.

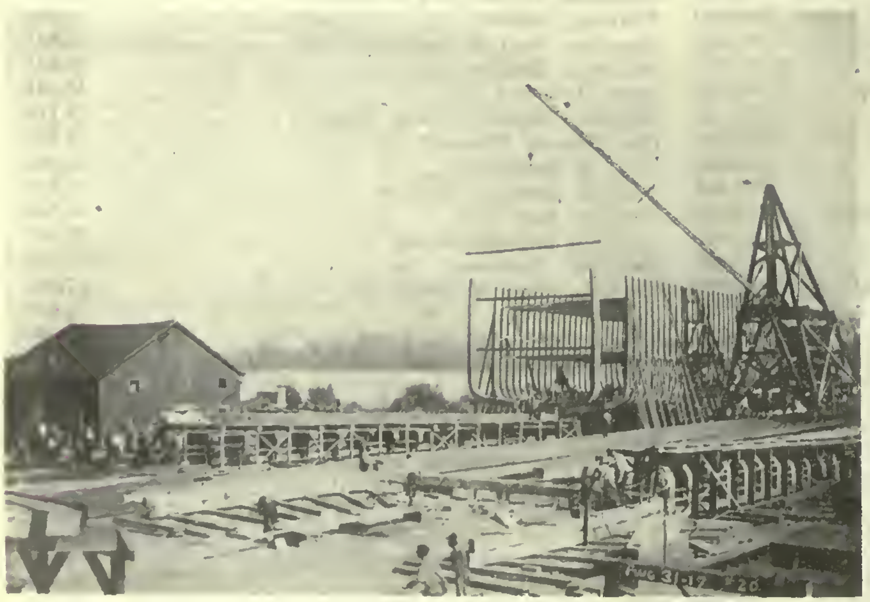


FIG. 1—WOODEN STEAMER IN FRAME

The hull is divided into several compartments by watertight bulkheads, which will materially assist in keeping the vessel afloat should it become damaged. About one and a half million feet of lumber was used in each boat, while for caulking over 350 bales of oakum were required.

The following brief description of the more important timbers will give an idea of the sizes of lumber used. Fig. 1 shows one of these boats being framed.

The keel is in four pieces all 20 x 24 in and from 54 to 76 ft. in length, the various lengths being joined together by scarps are carefully shifted in order also 20 x 24 in. and the sister keelson 24-ins. square. These sticks are in as long lengths as is practicable and the scarphs are carefully shifted in order to maintain the maximum possible strength throughout.

On the top of the wooden keelson there is a steel box girder keelson consisting of top and bottom plates 25 and 40 ins. respectively by ¾-in., web plates

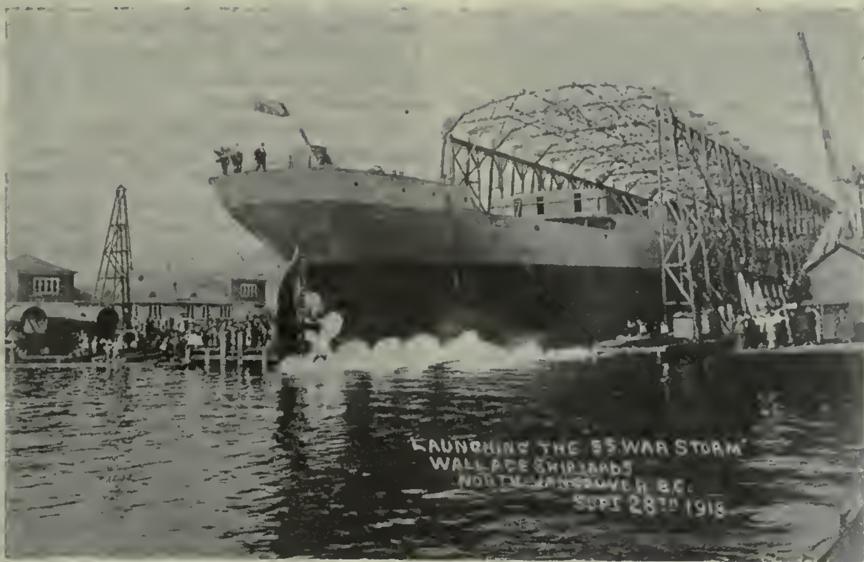

FIG. 2—LAUNCH OF "WAR STORM"

24-in. x ½-in., all secured by 6-in. x ½-in. angles.

The frames are doubled 12-in. sided and are tapered from 24-in. at the keel to 11-in. at the main deck. They are spaced 3 ft. centres. There are three garboard strakes, the first being 18-in. x 10-in. The planking is all 6-in.

The ceiling on the bottom is 12 x 10 in., on the turn of the bilge 14 x 14 in., and 12-in. x 10-in. and 8-in. on the sides. In order to avoid local weak spots the butts of the planking and ceiling are well shifted.

On the line of the hold beams there are two stringers each 14-in. x 16-in. and one clamp 14-in. square. The main deck stringer is composed of three strakes of 14in. x 14-in. These sticks are also in long lengths.

The main deck beams are 14-in. by 14-in., spaced 3 ft. centres, that is, one on every frame. The main deck is of 4½-in. x 4½-in. edge grain. Edge grain timber is used for decking on account of its wearing qualities, also there is no tendency to sliver. The narrow planking is preferable on account of the lessened amount of contraction and expansion to be taken care of at each seam. The upper deck is 3½-in. x 3½-in., also edge grain.

The propeller post is 30-in. moulded by 24-in. sided, being swelled to 32-in. at the shaft line. The shaft log, another large piece, is composed of two pieces of 36-in. x 18-in. To bracket the various parts together a large number of natural knees are used.

There are three cargo holds and one deep tank for water ballast, the holds and tanks being separated by water-tight bulkheads. The cargo holds are served by six steam winches operating through 5-ton derricks.

Some of the propelling machinery was procured in the East, the remainder being built by the Wallace Shipyards Ltd., of North Vancouver.

The engines are triple expansion, having cylinders 20-in. x 33-in. and 54-in. in diameter, with a common stroke of 40-in. and operate at about 70 R. P. M., developing 1,000 I.H.P.

The boilers are of the Howden water tube type, fitted with Howden's system of heated forced draught. About half the total number of boilers required were built by the Victoria Machinery Depot, of Victoria, B.C.

All the deck auxiliaries are products of British Columbia, the winches and windlasses being built by the Terminal City Iron Works, The North Shore Iron Works and Hutchison Bros. The steering gears, horizontal, double-geared machines, were built by the Schaake Co., Ltd., and Yarrows Ltd.

As previously mentioned, the shipbuilders were not responsible for the installation of machinery. This work was carried out by the Imperial Munitions Board at their own plant at Ogden Point, Victoria. The delivery of hulls, was, however more than fast enough to load this plant up, and to avoid delay several ships had their machinery installed at private yards.

On trials, with bunkers aboard, these vessels have made a speed of 11 knots per hour.

Three steel boats have been placed in commission by the Wallace Shipyards. These boats were built to the order of the Imperial Munitions Board and are 300 ft. long B.P. by 45 ft. mld. beam by 27 ft. mld. depth and carry 4,700 tons on a draught of 22 ft., 7 in. Fig. 2 shows the War Storm being launched in September.

With the exception of auxiliary apparatus in the engine room these boats are entirely British Columbia products. The main engines were built in the yards machine shop. The boilers were built by the Vulcan Iron Works at their plant on Granville Island. Deck winches and windlasses were built by the North Shore Iron Works, of N. Vancouver.

The vessels are of the well decked type with the machinery located amidships. Officers' quarters are on the bridge deck and crews' quarters in the poop. Extra large hatches are provided for convenience in handling cargo.

The engines are triple expansion with cylinders 24-in., 38-in. and 62-in. in diameter with a common stroke of 42-in. They are fitted with piston valves on the H.P. and I.P. cylinders and a double-ported, balanced slide valve on the L.P. The title cut shows a set of these engines in shop ready to be dismantled and installed in the boat. It will be seen that bridge columns are provided both back and front, giving a remarkably rigid job.

There are no pumps on the main engines, the idea being that the jobs could be turned out and installed quicker if these items were made independent. The circulating pump was of the centrifugal type, supplied by the Morris Machine Works. The condenser, made by the Wallace Shipyards, was built with a steel plate shell, rolled brass tube

FIG. 4—VULCAN IRON WORKS BOILER SHOP

plates and cast iron ends. It was supported on the back of the I.P. and L.P. columns by steel plate stools. The air and feed pumps were made by Dean Bros., of Indianapolis, and were supplied

FIG. 5—TRIAL TRIP DATA

by F. Darling & Co., of Vancouver. These pumps are of the simplex type, the main feed pump having a long stroke and being large enough to handle the work at very slow speed. The other auxiliary pumps were of the duplex type and were also supplied by F. Darling & Co.

Steam was supplied by two Scotch marine boilers 15 ft., 6-in. diameter by 11 ft., 3-in. long, working at 180 pounds per square inch. The total heating surface provided was 5,108, the grate area being 132 square feet, giving a ratio of 1 to 38.7.

The boilers were built by the Vulcan Iron Works. Fig. 4, showing one side of the main bay of their shop, shows the boilers for the War Storm among a number of others for J. Coughlan & Sons' ships.

On trial these boats have done up to 12 knots per hour, with bunkers aboard. Fig. 5 shows the trial trip data obtained on the War Power on June 27, 1918.

The machine shops of the Wallace Shipyards have been more than busy, for, besides engines for their own boats and repair jobs, they have turned out three sets of engines for the Imperial Munitions Board wooden ships. Two of these sets were also installed and the ships completed and delivered under steam at Victoria.

These engines differ from those in the steel boats in that the pumps are driven from the I.P. crosshead by single plate levers, and the condenser shell is of cast iron and is built-in.

The Wallace Foundry has furnished the castings for all this machinery as well as doing a lot of outside work, notably a contract, for 27 cast iron propellers for the Imperial Munitions Board.

FIG. 6—MOLD LOFT AT WALLACE SHIPYARD

An interesting job carried out by the yard was the lengthening of a couple of steel tug boats, the Point Grey and the Point Ellice. The former was built by the Wallace Shipyards and the latter by McDougall & Jenkins, now the North Shore Iron Works. They belong to the Department of Public Works and were employed as dredge tenders. On the dredging work being closed down they were taken over by the Imperial Munitions Board, Aeronautical Department, for towing spruce logs. As both the boats were built for harbor service their bunker capacity was not large enough for log towing, which would require the boats to be away from their base for about three weeks at a time They were both oil burners and it was decided to lengthen them and build in additional oil tanks.

The boats were both hauled out on the large ways at the same time, the ends separated and the new portion built in. The boilers were then shifted aft to the same relative position in relation to the engines which they occupied before, and a new oil-tight bulkhead built forward of them. The space thus provided between the old and the new bulkheads gave ample capacity for the fuel oil.

As the boats were short, 100 ft. and 91 ft., 6 in. respectively, and very fully powered, some interesting calculations were entailed to ensure, that when lengthened, they would trim properly.

The Wallace Shipyards plant has recently undergone extensive alteration and extension, a new plate shed and mold loft being constructed. Fig. 6 shows the latter, which is 186 feet long by 80 feet broad. It is located above the plate shed, which is equipped with a mono-rail system for handling plates, etc. Three building berths have been provided, capable of taking vessels up to 400 feet long.

The system of handling material from the plate shed to the building berths is by standard gauge railroad running between the berths. At each end of the berths a tower is located under which the tracks run. The towers are 48 feet high and each tower carried a pair of derricks equipped with 80-ft. booms. As the towers are high enough to permit the boom to swing across the deck of a ship, it appears to be an excellent system.

The work of extension has been carried out by Messrs. Hodgson and King, contractors, of Vancouver.

The Wallace Shipyards have at present under construction two steel boats of 4,300 tons D.W. and two of 5,100 tons D.W. for the Dominion Government.

The former are 320 ft. long B.P., by 44 ft. mld. beam, by 25 ft. mld. depth, and are designed to carry their deadweight on a mean draught of 21 ft., 2 in. A 6 hour loaded trial is called for and a speed of 11½ knots is to be maintained.

Accommodation is provided for 34 officers and men, the former being berthed in deck-houses on the bridge deck amidships and the latter aft.

11 steam winches and an anchor windlass are provided for handling cargo and anchors. These auxiliaries are being built by the North Shore Iron Works.

The propelling machinery consists of a set of triple expansion engines having cylinders 25 in., 41 in. and 67 in. with a common stroke of 45 in., the air, feed and bilge pumps being driven from the L.P. crosshead.

Steam is supplied by two single ended Scotch marine boilers 15 ft., 6 in. diameter by 11 ft., 6 in. long, working at 180 pounds per square-inch. The boilers are operated under heated forced draught, the well known Howden's system of closed ashpits being used.

The 5,100-ton steamers which this firm is building for the Dominion are of the type "C" of the standard series. They are 331 ft. B.P. by 46 ft., 6-in. mld. beam by 25 ft., 6-in. mld. depth, and have a mean draught of 21 ft., 8 in.

A speed of 12 knots loaded is specified. The main engines being 25 in., 41 in., and 68 in. by 45 in., with air, feed and bilge pumps attached, the circulating pumps being of the centrifugal type driven by a small independent engine. There are three boilers 14 ft. diameter by 11 ft., 6 in. long, working at 180 pounds per square-inch. The boilers are operated under forced draught, approximately 7,275 square-

FIG. 7—HULL OF THE MARGARET HANEY, AUXILIARY POWER SCHOONER, UNDER CONSTRUCTION

feet of heating surface being provided. The arrangement of the boilers in the ship shows the three abreast, consequently there are no side bunkers in either the engine room or stokehold. Permanent bunkers are provided under the bridge deck and a large cross bunker forward of the stokehold. On short passages the latter could be used for cargo.

The boilers for these boats as well as those already turned out will be built by the Vulcan Iron Works at their plant on Granville Island, Vancouver. The Vulcan Iron Works, have since the destruction by fire of the boiler shop at the shipyard of J. J. Coughlan & Sons, supplied that firm with boilers for their vessels. This boiler shop is fully modern in every respect, having been built within the last few years and recently extended.

The equipment consists of a three ram flanging machine, a 12 ft. plate bender, and a large riveter, all operated by hydraulic power. Drilling holes, the usual bugbear of the boiler shop is very well taken care of, a two-head, movable column drilling machine being provided for shell drilling and several radial drills being available for combustion chamber work. One of the recent additions to the plant is the machine shop in which all tools are made, stays threaded and work of a like nature carried out.

The plate furnace, for annealing the large end plates after flanging is rather

VIEW OF J. COUGHLAN & SONS' SHIPBUILDING PLANT, VANCOUVER, B.C., SHOWING FROM LEFT TO RIGHT:—SS. WAR CAMP, SS. WAR CHARGER, SS. WAR CHIEF

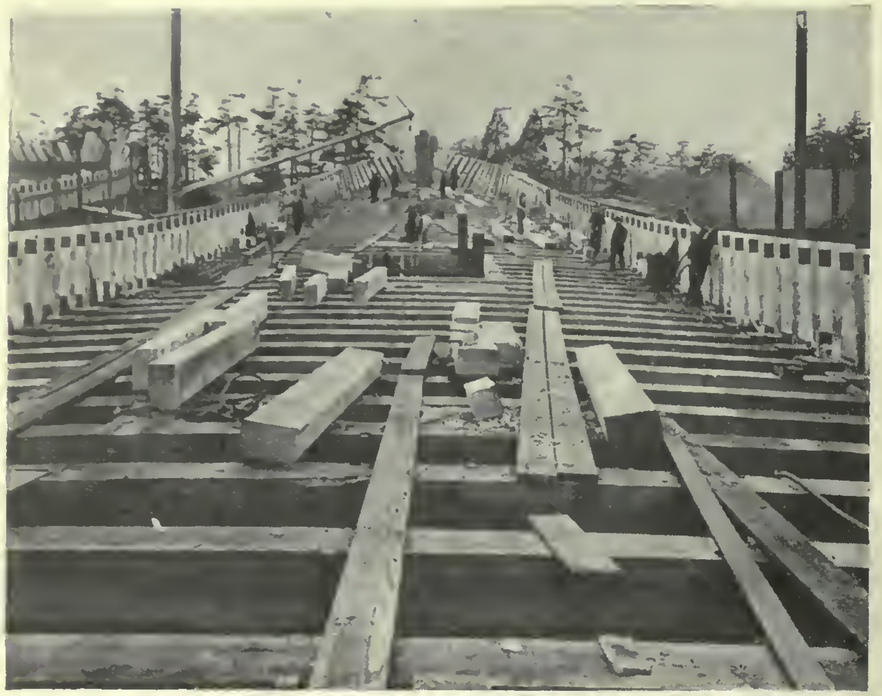

FIG. 8—DECK VIEW OF AUXILIARY SCHOONER

interesting in that the fuel used is slabs, which are obtained as refuse from the local sawmills. The rivet heating furnace at the hydraulic riveter uses the same fuel. Both have given every satisfaction. They were installed by Mr. T. A. Thomas, of Nanaimo, B. C.

Besides the large marine boilers, the Vulcan Iron Works have handled a lot of other work, among which was the finishing of the rudders for the Imperial Munitions Board wooden ships, the hydraulic riveter being used for riveting the plate to the arms. A number of smoke stacks and uptakes were also built for these boats. Two large locomotive boilers were built for the Canadian Collieries (Dunsmuir), Ltd., who operate an extensive coal field on Vancouver Island. These boilers were installed in existing locomotives, the boilers of which were worn out. A number of large digesters were also built for a local pulp mill.

Fig. 4 shows one side of the main bay of this plant and the string of boilers 14 ft., 9 in., and 15 ft., 6 in. in diameter proves that the manufacture of this type of kettle is well established in British Columbia.

The Wm. Lyall Shipbuilding Co., Ltd., of N. Vancouver have, since the completion of their contract with the Imperial Munitions Board, been working for their own account on a programme of six auxiliary powered schooners.

These boats are five-masted topsail schooners, and, with the exception of the addition of topsails and some slight alteration to the sheer line and deck houses are the same as the first boats built in this yard when it was established as the Wallace Shipyards Plant No. 2.

The schooners are 225 ft. long on the keel by 44 ft., 6 in. extreme beam by 20 ft., 9 in. mld. depth. They will carry about 2,500 tons D.W.

Three of these boats are fitted with twin Atlas Diesel engines of about 175 B.H.P. each, the remaining three with Fairbanks-Morse semi-Diesel engines of 200 B., H. P. each.

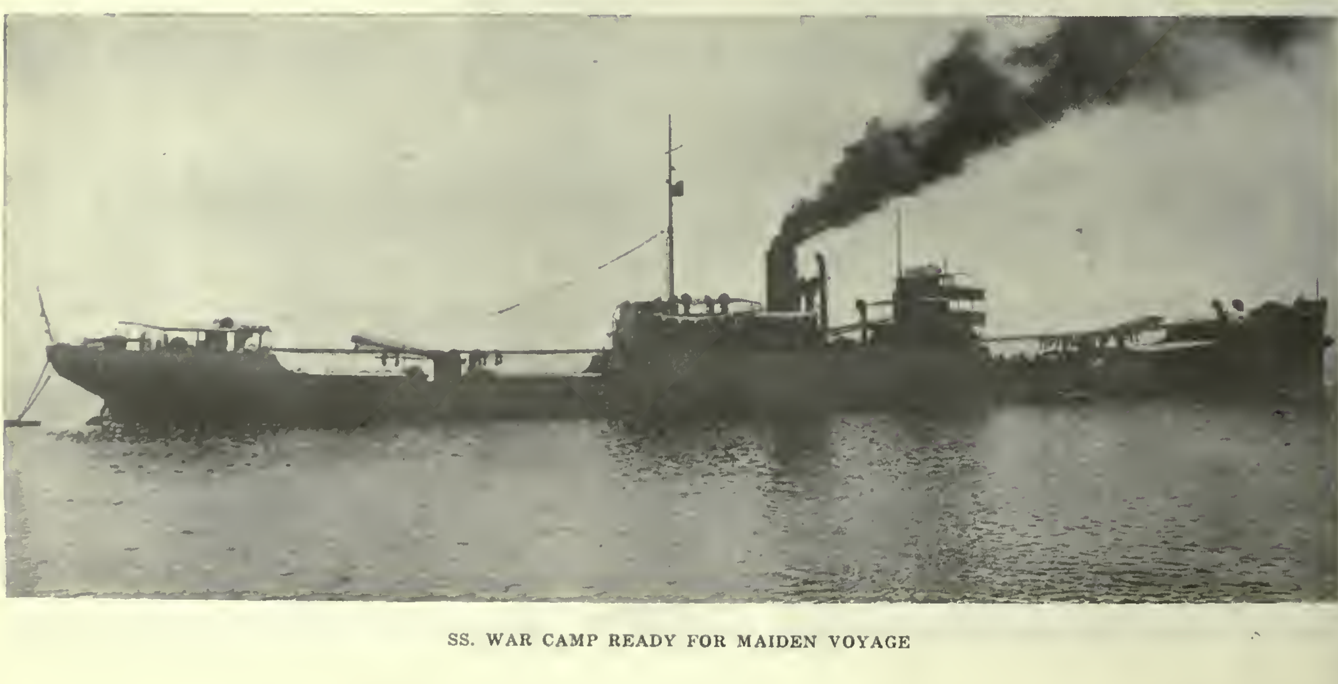
At the time of writing three of the schooners have been launched and were in various stages of completion. The others will probably all be launched by the end of the year.

This yard is equipped with six building berths and as they are vacated by the schooners, keels are being laid for a contract for eight steamers for French interests.

The dimensions of these boats will be 195 ft. B.P., 204 ft., 6 in. over all by 39 ft., 8 in. mld. beam by 17 ft. depth of hold and on a mean draught of 16 ft. will carry about 1,500 tons D.W.

Two masts are provided and are fitted with two derricks each for cargo handling. The deck auxiliaries comprise six cargo winches by M. Beatty & Sons, an anchor windlass by the Terminal City Iron Works, of Vancouver, and a steam steering gear by the Schaake Co., Ltd. The steering gears are of the same type which this firm supplied to the Imperial Munitions Board for their wooden ships.

The propelling machinery consists of two sets of compound engines having cylinders 12 in. and 24 in. with a common stroke of 16 in. The engines are being supplied by the Sorel Mechanical Shops, Sorel, Quebec. They are arranged back to back in the ships with the operating gear led to the space between them. At their rated speed an



SS. WAR CAMP READY FOR MAIDEN VOYAGE

WOODEN SCHOONER ALICE BEAUCLERC ON THE WAYS

output of 550 I.H.P. will be obtained. There are no pumps attached to the engines, all auxiliaries being independent.

Steam is supplied by a Scott water tube boiler having 2,012 square-feet of heating surface, 56 square-feet of grate area, giving a ratio of about 1 to 36. Steam for cargo handling is supplied by a smaller boiler of the same type operating at 125 pounds working pressure.

Twelve more ships of a similar description, and for the same owners are being built in British Columbia. They are apportioned as follows: Western Canada Shipyards, 5; New Westminster Construction & Engineering Co., Ltd., 5; Pacific Construction Co., Coquitlam, 2.

At one time prominent in the steel construction business, Messrs. J. J Coughlan & Sons have, for the past year or so, given their entire attention to their shipyard on False Creek. This yard is the largest shipbuilding plant on the coast. It is equipped with four building berths which are all completely covered in. The berths are each provided with three sets of runways for travelling cranes. The covered berths make efficient work possible in all conditions of weather. Although British Columbia does not suffer from intense cold during the winter, there is enough rain to render a covered building berth a very good investment. The plate shed with the mold loft above is located west of the berths and material is handled from the shed to under the travelling cranes by trucks running on standard gauge track.

While this firm does not build their own machinery a good-sized machine shop is provided. In the machine shop the hundreds of small fittings are made, as well as the propellers, stern tubes, etc.

As originally laid out a boiler shop was included in the yard and in it the boilers for the Alaska, the first boat turned out, were built. The boiler shop was, unfortunately, destroyed by fire and the heavy hydraulic machinery, so necessary for the construction of large marine boilers, was a total loss. As it was practically impossible to replace the machinery it was decided to hand this part of the work over to the Vulcan Iron Works.

J. J. Coughlan & Sons have three boats in commission, two in the water being fitted out, one ready for launching and four in various stages of construction. Thesee boats are 427 ft. long B.P., 54 ft. mld., beam 29 ft., 9 in. mld depth and carry 8,800 tons D.W. on a draught of 25 ft., 2 in. When complete they make a very fine looking boat and are fitted up and finished in first-class shape. As a matter of fact it has

SS. WAR CHARGER AT NO. 2 FITTING OUT BERTH been remarked by people who are able to judge and who have seen the work in both ends of the country, that the workmanship turned out in British Columbia is superior to that of the East, both in regard to hull and engine and boiler work.

The engineer's accommodation is located on the after end of the bridge deck alongside the engine room casing. The captain's and mate's quarters being at the forward end, in the saloon.

The deck auxiliaries comprise ten cargo and one warping winches, which are being supplied by the North Shore Iron Works, an anchor windlass and a steam steering gear. The latter is driven by a double cylinder engine and is located in the poop, being operated under telemotor control from the bridge.

The ships are all driven by geared turbines, four sets being supplied by the Kerr Turbine Co., of Wellsville, and are of the impulse type. The other six are of the Parsons type. Both types are equipped with double reduction gearing, the Parsons turbines being in two units and have astern elements in each. At rated speed and pressure the turbines give approximately 2,650 S. H. P. The propellers are 14 ft. diameter and turn up 100 revs. per minute, giving a loaded speed of 10½ knots per hour.

Steam is supplied at 190 pounds per square-inch by three boilers 14 ft., 9 in. diameter by 10 ft., 6 in. long. The boilers are operated under forced draught and are equipped with Foster superheaters, a superheat of 50 deg. F. being maintained. The forced draught outfits are supplied by the Jas. Howden Co., of Glasgow, Scotland. The fans are provided with double engines As these engines have to run at a fairly high speed for long periods, the provision of two engines enables them to be overhauled at sea. The change over can be effected in a very few minutes.

Crompton's ash hoists are employed for the disposal of ashes. These hoists raise and dump the ashes automatically through a chute leading to the ship's side and form one of the most convenient and cleanly methods of getting rid of ashes.

Single collar thrusts of the Kingsbury type are employed on the shafting, the thrust bearing being made by the Canadian Westinghouse Co.

The main condensers, containing 4,000 square-feet of cooling surface are supplied by the Wheeler Condenser & Engineering Co. They are equipped with radio-jet air extractors, circulating water being handled by a 14-in. Morris Machine Works centrifugal pump.

On completion of their present work, Messrs. J. J. Coughlan & Sons will be engaged on Dominion Government work, having secured contracts for the construction of vessels of 8,100 tons D.W.

These boats are the type "B" of the standard series. They are 400 ft. long B.P. by 52 ft. mld. beam by 31 ft. mld. depth, and carry their deadweight on a mean draught of 25 ft., 1 in. They will have a speed of 11¾ knots per hour.

The hull is divided by six water-tight bulkheads and the usual double bottom is provided, the double bottom under the machinery space having a water-tight centre-line. Accommodation is provided for a complement of 47 officers and men. Rather more than the usual care has been bestowed on the accommodation, and there is no doubt that these boats, as well as those which are being built by the Wallace Shipyards for the Dominion Government, will be a credit to Canada. The steam steering gear is located in the poop and is of the guided segment type, controlled by telemotor from the bridge. Cargo handling is provided for by ten 7-in. by 12-in. double cylinder single drum winches, the winch on the bridge deck and that on the poop deck having extended shafts carrying warping barrels. A quick warping type anchor windlass is located on the forecastle deck.

It might be mentioned that in going over modern ship specification the absence of reference to copper pipe is noticed. It used to be considered that copper was the only suitable material for steam and feed pipes. In all the boats built in British Columbia mild steel pipe has been used for these purposes, and none of it has given any trouble.

The propelling machinery is a triple expansion engine having cylinders 27 in., 44-in., and 73-in., with a common stroke of 48-in. and is rated at 3,000 I. H. P. The H. P. and I. P. cylinders are provided with piston valves and the L. P. with a double-ported slide valve.

A circular steel plate condenser, built on the contraflo principle, is provided containing 3,000 square-feet of cooling surface.

LAUNCH OF THE HELEN LYALL

The air, feed and bilge pumps are attached to the engine. The air pump being 24-in. by 24-in. and of the Edwards type. The feed and bilge pumps are each 4-in. by 24-in.

Steam is supplied by three single ended marine boilers 15 ft., 6-in. diameter by 11 ft., 6-in. long working at 180 pounds per square-inch. The boilers are operated under a system of heated forced draught. They are arranged abreast in the ship with no permanent bunker space in the stokehold below the twin deck.

The Foundation Co., of British Columbia, who established a shipyard in Victoria to build wooden ships for the Imperial Munitions Board, have recently taken over the plant of the Cameron-Genoa Shipbuilding Co. The latter plant was established to carry out a contract for six auxiliary schooners for the Canada West Coast Navigation Co., and later built several wooden steamers. It was on the completion of this work that the yard was taken over by the Foundation Co. Views are shown of one of the auxiliary schooners being built by the Cameron-Genoa Shipbuilding Co.

This yard has accepted contracts for twenty wooden steamers for French interests. The yard will be able to lay down ten of the boats at one time. The boats will carry about 2,500 tons D. W., and will be propelled by twin engines 14-in., 23-in., and 38-in by 24-in. stroke, giving a total of about 1,100 I.H.P.

The boats will be built throughout to the rules of the Bureau Veritas and that society's surveyors will also superintend the work of construction.

Yarrows, Ltd., of Esquimault, have continued turning out shallow draught stern wheel steamers for shipment to the far East. Their proximity to the Government drydock at the Navy Yard enables them to adequately handle large repair jobs. The Japanese steamer Canada Maru, which ran ashore in the Straits of Juan de Fuca, has just been repaired by them. This was a very expensive job, the cost running to over half a million dollars. The Princess Adelaide, one of the Canadian Pacific Railway Cos'. coasting passenger boats, was recently badly damaged on the rocks near Active Pass. She is at present in the hands of Yarrows, Ltd., for repairs.

Of the making of ships there is no end. Also there seems to be no end of things required to build and furnish a ship. There are very few trades which have not felt the stimulus of ship work. Winches, windlasses, ash hoists and all kinds of similar machinery can be seen in the various smaller machine shops, being made for local use and also for export.

The North Shore Iron Works have recently completed export contracts for winches and windlasses and the Schaake Co., have lathes which practically never stop, being kept busy on shafting forgings sent up from across the International Boundary and returned in a completed state for use in Uncle Sam's ships.

Whether British Columbia can continue in the steel shipbuilding business when competitive conditions are restored is a question often asked. There are only two reasons for an answer in the negative.

The logging camps and lumber mills are working full blast getting out material for wooden ships. As long as steel, which is, of course, the logical material for shipbuilding, remains difficult to obtain, wooden ships will be built and British Columbia is the right place to build them. A lot of adverse criticism was levelled at wooden ships when the idea of building them was first promulgated. Properly designed and built and reasonable care taken to prevent attacks of dry rot from the inside and of the torpedo from the outside, there is no reason why the ships that have been built and those that will be built should not have a long and useful life and be a credit to their constructors.

The enormous freight bill entailed by the rail haul from the Eastern States, where the bulk of the raw material is produced is a big item in the cost. This can be got over in two ways. There are large deposits of iron ore in British Columbia, there is lots of coal and limestone. Can British Columbia produce her own ship plate? In a very short time ship plates will be rolled on the Eastern Canadian seaboard and a considerable reduction in the freight bill ought to be obtained by shipping the material via Panama. This might prove a profitable cargo for the ships now being built for the Dominion Government.

The second item to be overcome is the higher cost of wages in the West. To overcome this perhaps the best solution is to give more for the wages paid. Not only the workman but every man in the yard, from the management down, must give an intelligent and cooperative day's work. By producing more the cost of production will be reduced. If we are to keep our yards going we must be prepared to offset the higher cost of labor by more efficient work. If we can do this we can compete successfully.

COMBINED RAIL AND ROAD TRUCKS

A scheme of which particulars were developed by Mr. Thomas Bennett, of Trelabe, St. Albans, England, contemplates the use of combined rail and road trucks. He would collect "loaders" provided with wheels which would permit them to be hauled over ordinary roads. On arriving at a station by road these loaders would be taken to a bank or platform raised to such a height as to be level with the flat tops of wagons or "chassis" running on the railway track. On this bank each of their wheels would be placed on "laterals" furnished with four small wheels or rollers and then they would be moved upon the chassis and secured in place. On reaching its destination the train would be taken alongside a similar bank and the loaders would be pulled off the chassis and removed from the laterals, to be subsequently delivered by road. Mr. Bennett claims various advantages for his plan, including saving of shunting and of handling goods, but whether or not these could be realized in practice the permissible height of the loads he could carry would be less than at present, owing to the limitations imposed vertically on the loading gauge by bridges and tunnels, and probably also the gross weight of the trains would be greater in relation to the paying load.

EFFICIENCY IN BELT DRIVES

In almost every factory and machine shop a certain amount of power is wasted in transmission through driving belts, the percentage of loss depending on the attention paid to the matter. Slipping, the trouble most frequently encountered, is common to all classes of belting, and generally speaking the remedy applied is to cut and tighten, or "take up," the belt, so that it will run free from slackness with a better grip of the pulley; but probably more belts are broken and prematurely destroyed in this way than by actual use, not to speak of additional load thrown on the engine and the consequent waste of power. To overcome slipping many engineers incline to the principle of using belts wider than is actually necessary. This permits a heavier load to be carried, but when the practice is generally adopted all over a machine shop with 50 or more belt drives, the cost is very considerable. There is, however, a growing tendency to run belts slack, as not only is friction thus reduced and the life of the belt increased, but no power is wasted and the strain on the prime mover is considerably reduced. Immediately the tension is reduced the friction is proportionately lessened. Further increase of the arc of contact round the pulley (after the belt has been sufficiently slackened to have no initial tension) will not lessen the friction, but the load-carrying capacity of the belt is increased. As an example, in many engineering shops it has been found that cuts 50 per cent. heavier can be taken on lathes where the arc of contact has been increased from 180° (with a tight belt) to as high as 220° (with a slack belt), and in one instance with a corn-crushing machine the increase in output was over 50 per cent. To permit of driving belts being run slack a proper belt dressing should be employed. Many belt dressings rely almost entirely on their capacity to "stick," due to the inclusion of rosin or tar in their composition. but others take the form of a non-stick preservative or belt food, free from acid or alkali action, which is absorbed into the belt. rendering it pliable and highly effective, and at the same time protecting it from the effects of moisture, dryness, or chemical fumes. Such a preparation properly applied tends to give belts a velvety cling through the setting up of a vacuum suction between the belt and the pulley face. and will permit of slack running without fear of slip, even under the heaviest loads.

Canada Controls Nickel Output of the World

Plant of the International Nickel Co. of Canada, Ltd., at Port Colborne, Plays an Important Part in Holding This Industry in All Its Stages to This Country Assures Canadian Control of Metal

By W. F. SUTHERLAND

View of refinery, showing main smelter building, machine shop, part of power house and nickel refinery.

FROM the earliest times, when man first emerged from the stone age, down to the present, iron and copper have been essential to his well being and progress. Other metals, amongst them tin, lead, and zinc, have also been of much value to him throughout the ages, but it is only within the last century that nickel has assumed the importance its properties entitle it to. By itself, its brightness, non-corrosive properties and hardness render it one of the most useful of metals, and alloyed with iron, it is almost indispensable in the present war.

The importance of nickel in the recent war lends particular interest to the refinery of the International Nickel Co. of Canada at Port Colborne, the first refinery to be built on Canadian soil, and its successful establishment marks a new epoch in the industrial development of the Dominion. It has long been recognized that it would be of great advantage to the country and to the Empire at large to have Ontario's nickel industry self-contained within the borders of our own province, and an agitation has been carried on for many years with this object in view. Economic conditions have, however, in the past prevented the attainment of this very desirable object, the long freight haul, and tariff on the necessary fluxes and other materials needed in refining have made it out of the question to refine at the mines. War conditions rendered it imperative that Canadian nickel be refined in Canada, and, after considerable study, Port Colborne was selected as a site where freight and other expenses could be reduced to a minimum, the longer haul on the materials imported being, in some measure, counterbalanced by the shorter haul from the smelter on the copper-nickel matte. Full advantage is also obtained from the lower cost of water haulage.

OFFICE BUILDING, INTERNATIONAL NICKEL CO. OF CANADA, REFINERY, PORT COLBORNE

Together with the establishment of the refinery at Port Colborne, the Canadian Copper Company underwent a change in its organization, becoming entirely a subsidiary of the International Nickel Company of Canada then formed. It may be emphasized that this company is not an American organization and that its policy is to employ Canadian engineering talent and labor as far as possible, a feature contemplated for a good many years, ever since the desirability of establishing the refinery in Canada was considered by the personnel of the company.

At the present time 34.5 per cent. of the payroll is Canadian, 1.8 per cent. American, 3.5 English, Irish and Scotch, and the remainder various nationalities, including some Chinese, a necessity arising from the present labor shortage.

Mr. More, the general manager of the plant, stated that his policy was to give employment to the returned soldier wherever possible, and that the results secured were quite in agreement with those experienced by other employers, their work in the main being very satisfactory, although considerable restlessness was much in evidence.

The most pressing problem to be faced in refining nickel is to secure labor, means to prevent the constant transfer of trained and partially trained help to other employment, necessitating the training of inexperienced men, and a consequent loss of efficiency would be welcomed. "We have the plant, and now we need the men," was Mr. More's summary of the situation. With all else provided for, the securing of labor is the largest issue to be faced in bringing about a rapid expansion in production in the newly-established Canadian nickel-refining industry.

Nickel as a Mineral

The geology of nickel and the location of the various deposits throughout the world are of considerable interest, and a knowledge of the mining and smelting of the ores is of value and may well precede the description of the refinery proper.

Contrary to popular belief, nickel-bearing ores occur in widely separated countries, Canada and New Caledonia having by far the largest and best deposits The United States has some workable deposits which were worked for many years until competition from New Caledonia rendered it unprofitable. These deposits are located in widely separated parts of the country, and some is still being obtained from the blister copper refined at Perth Amboy, near New York.

One other country in the Western Hemisphere may some time in the future prove to be a valuable source of nickel steel, since the vast iron ore deposits of the eastern end of Cuba carry enough of that metal to add to the value of the steel produced from its ores.

Nickel has long been obtained from European deposits, which were naturally the first sources to become known to the scientific world, although nickel alloys, pakfong, had been used by the Chinese long before. The first nickel was obtained by Crondstedt in 1751 from ores containing nickelite associated with cobalt minerals from Helsingland, Sweden; and a small amount of the metal is still being obtained from this source, though much less than from the neighboring country, Norway.

Norway contains no less than forty distinct outcrops of nickel-bearing ores, although at the beginning of the war only one mine was in operation. The ores are somewhat lean, containing only about 1.5 to 2.5 per cent. of nickel in the form of sulphides.

A number of other European deposits are of interest, such as the deposits in Piedmont and others near Horbach and Totmoos in the Grand Duchy of Baden, where ores containing 12 per cent. of nickel are found. Ores near Bilboa, in Spain, are reported to carry 6 per cent. nickel, 7 per cent. copper, and 3 per cent. of cobalt.

The deposits of nickel in Sweden, Norway, and particularly in the Duchy of Baden merit considerable attention at the present time, as it is altogether likely that much of Germany's war needs of nickel were supplied from these sources.

Nickel Ores of New Caledonia

Next to the Sudbury region the French colony of New Caledonia, 900 miles east of Australia, is the most important source of nickel in the world, the deposits having been first discovered in 1865 by Garnier. Deposits of nickel, cobalt and chromium are found in large beds on gentle slopes or basins on the flanks of the mountains; the nickel occurring as a hydrated silicate in which

JOHN MORE,
General Manager, International Nickel Co. of Canada, Refinery, Port Colborne.

the nickel has replaced magnesia to a greater or less extent. The richest silicates, which are green and soft, may contain up to 48.6 per cent. of nickel oxide, but their composition varies greatly.

It is interesting to note that the New Caledonia ores practically never contain sulphur, being silicates accumulated in beds through the weathering of the original rocks, while the nickel deposits at Sudbury are in the form of sulphides associated with those of iron and copper.

The Sudbury Region

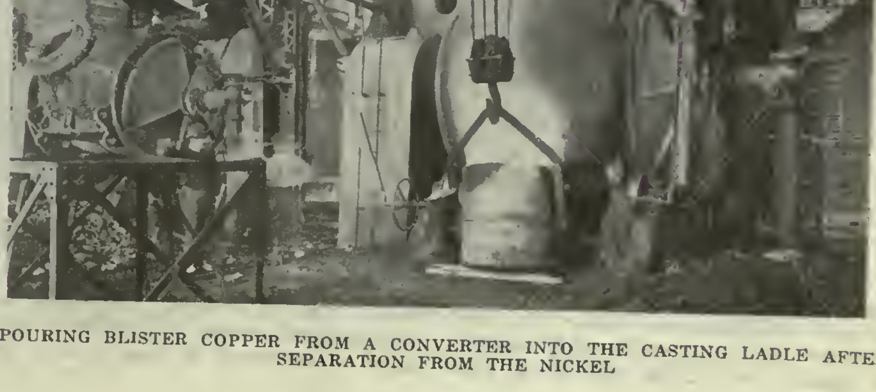
Sixty years ago, Northern Ontario, then a part of Upper Canada, was a wilderness, known only to a few Indians who made a living as best they might by hunting, fishing, and trapping. The timber resources of the country were untouched, the vast mineral resources were unknown, and the fertile farm lands of the clay belt were thought non-existent.

The first intimation that valuable ore deposits might be found in the regions at the head of Lake Huron was made in 1848, in a report by Sir William Logan, then provincial geologist. He mentioned the fact that in one instance copper pyrites was accompanied by compounds of iron and nickel, with a trace of cobalt and stated that it would appear singular that a region extending over a space of between one and two thousand square miles, and giving marked indications of mineralization, did not, in the course of time, yield man valuable results.

From that time onward, various discoveries of copper and nickel-bearing ores were reported by various geologists and surveyors, who traversed the country, nickel being found at several places somewhat remote from what is now known as the Sudbury region. Nickel was first reported from this region by Murray in 1856. The well-known land surveyor Salter first reported indications of iron near the present Creighton mine, the greatest nickel mine in the world, his compass needle being very materially deflected by the iron with which the nickel is associated in the ore, and at his suggestion Murray investigated the deposit, finding copper and nickel.

As is often the case, the opening up of a country by improved transportation leads to its rapid development, and the utilization of its natural resources. The running of the Canadian Pacific in 1883 through the Sudbury district in this particular instance effected the discovery of important nickel deposits, as in the making of a cutting the excavation was carried through the ore body of what was afterwards known as the Murray Mine.

This exposure on the C. P. R. right of way gave the public some inkling as to



POURING BLISTER COPPER FROM A CONVERTER INTO THE CASTING LADLE AFTER SEPARATION FROM THE NICKEL

INTERIOR VIEW OF LABORATORY—ALBERINE FUME CABINETS AND TABLE TOPS ARE USED

the value of the minerals to be found, and the country was quickly prospected, most of the important deposits of nickel and copper ores being found in a short time.

Geology of the Sudbury District

The nickel region has sharply-defined boundaries of a geological nature, since all the ore deposits are connected with a great sheet of eruptive rock, roughly boat shaped. Only the upturned edges of the sheet are exposed, since it is basin shaped and has its interior filled with sedimentary rocks. The basin is thirty-six miles long and about sixteen miles wide, and the known ore deposits are all either along the edge of the sheet, or less than four miles away from it on projections or offsets.

The Sudbury ores contain essentially only four ingredients, a magnetic sulphide of iron, which is practically free from nickel and copper, a sulphide of nickel and iron, a sulphide containing equal parts of iron and copper, and a variable amount of rock matter of several kinds. Some of the ores are low in copper and high in iron, and if these could be selected so as to contain only a minimum amount of copper, the large amount of iron present in the ore could be used directly in the production of nickel steel and much expense avoided. Recent researches have demonstrated that under certain conditions copper is not detrimental to steel, and it is possible that some method may be developed which will render possible the saving of the iron content in the form of a steel containing both nickel and copper.

The Canadian Copper Co.

The history of mining and smelting in the Sudbury region is so closely bound up with the Canadian Copper Co., now absorbed by the International Nickel Co. of Canada, that a good idea of the processes connected with the smelting of the ores may be gained by following the various operations as they are conducted at this company's smelter at Copper Cliff.

The valuable constituents of the ores are nickel and copper, and these two metals must first be separated from the useless materials and then from one another. The first step is the elimination of much of the sulphur found in combination with the nickel copper and iron of the ore, and in the past this has been largely accomplished by heap roasting, although it is anticipated that this process, destructive to vegetation and wasteful of sulphur, will soon become a thing of the past. For heap roasting, a flat, well-drained surface is prepared, and a layer of cordwood or dead pine is laid down to a depth of a foot or eighteen inches. On this bed coarse ores are placed, followed by medium ores, and finally by fines. The heap, when completed, contains up to 2,000 or 3,000 tons, and has a trim, rectangular shape, with flat top and sloping sides. The wood is set fire to and burns out, by which time the sulphur is ignited and burns without further assistance. The larger heaps require three or four months to burn, and at the end of this time all but about 10 per cent. of the sulphur has burned off and the iron is more or less completely oxidized.

After roasting, the ore is smelted in water-jacketed furnaces to standard matte. These copper blast furnaces are rectangular in shape and can handle about 500 tons of ore per day. The ore from the several mines owned by the company, owing to the large proportion of iron and admixture of rock with the sulphides, can be blended to form almost self-fluxing mixtures, but quartz is added as required to produce a further oxidization. The smelting results in two products, matte and slag. The matte contains practically all the nickel and copper, with much of the iron. The matte from the blast furnace is next poured into basic converters, where the remaining iron is oxidized in much the same manner as is the carbon in the familiar Bessemer converter of the steel mill. The iron passes out in the slag resulting from the operation, and a standard matte ready for refining results. This matte contains very nearly all the nickel and copper, very little of the iron, and a high percentage of sulphur. The matte is sent to the refinery at Port Colborne, where the copper and nickel are separated and refined.

THE PORT COLBORNE REFINERY

On approaching the refinery one is favorably impressed with the excellent architectural features of the administrative and other buildings forming a group at the entrance.

INTERIOR OF MACHINE SHOP

COTTRELL PRECIPITATION PLANT—SEVEN 25 KW., C.G.E. MOTOR GENERATOR SETS SUPPLY ALTERNATING CURRENT TO THE STEP-UP TRANSFORMERS

The comfort and health of the large staff have been given considerable care, and the result is shown in the staff house provided for employees, and in the club house for the accommodation of the unmarried department and executive heads. This latter building contains recreative features such as bowling alley and billiard rooms, in addition to the living accommodations provided.

Adjacent to the administrative building is located the combined garage, timekeeper's office, and hospital. The garage forms the lower or basement story, with the timekeeper's office immediately above. The hospital forms a somewhat detached portion of the building and is an extremely well appointed and necessary part of the plant. Its need may be realized when it is known that the nearest hospital of any kind is at Welland, some nine miles away. An examination room is provided for the reception of the patient and for the administering of first aid; a ward room is also in readiness for any bed cases, and a completely-equipped operating room with table and sterilizers has been fitted out.

Laboratory

The laboratory is housed in a separate two storey and basement building, and besides the offices necessary, contains the man laboratory and balance rooms. The laboratory has been fitted throughout with alberine or soapstone tables and a central fume hood with ten compartments has been arranged around a central stack. Each compartment is also constructed of alberine and has wire-inserted plate glass sliding doors with marble trim. The balance room is equipped with the usual precision and assay balances carried on an alberine slab free standing from the building, and supported on brick piers carried to bed rock.

Transportation Facilities

Railway sidings from the Grand Trunk enter the company's property from the north. These sidings serve every portion of the plant, and all handling of materials by hand being eliminated.

The furnace building, known as the No. 1 building, is 746 ft. in length by 125 ft. in width, and at present houses three blast furnaces and three convertors. The matte received from the smelter at Copper Cliff undergoes its initial treatment here, and the method of handling the raw materials is of interest. The matte, coke and fluxes are brought in on an elevated trestle of reinforced concrete, and which displays excellent design and workmanship. From the cars the materials are dumped into elevated storage bins, from which it goes to the feeding floor and thence to the furnaces. The standard matte, 55 per cent. nickel and 24 per cent. copper, is smelted with saltcake, the nickel separated and the copper bessemerized in the convertors. These convertors are of Allis-Chalmers make, and are of 84 in. by 126 in. size. Electric tilting gear controls their movement. Besides these convertors this company supplied two sets of crushing rolls and a sample grinder.

Removal of Fumes and Gases

In the various operations conducted in the No. 1 building much sulphur is given off in the form of sulphur dioxide gas, and to remove this and disperse it in such a manner as to prevent damage to vegetation has been a problem of some magnitude. Each convertor has a stationary hood and also a movable one for use when pouring, through which all of the deleterious gases are removed and conducted to the stack. For the removal of dust and a valuable metallic content, the gases, before entering the stack, are subject to the familiar Cottrell precipitation process.

The Cottrell Precipitation Process

For many years there was no known process by means of which dust and other objectionable matter in flue gases and in the gaseous products of metallurgical operations could be completely eliminated. The Cottrell precipitation process, a somewhat recent development, has been applied to these uses with such success, however, that it has been well established as a standard means of removing fine particles of material such as dust, fumes, acid, mists, etc., from the gases resulting from the smelting and refining of copper, lead, zinc, and other metals.

The installation of this system in the refinery at Port Colborne is one of the largest and most successful in North America, and is admirably planned for the work it has to do in the elimination of many of the noxious elements of the gases and in the recovery of valuable metals.

A brief description of the fundamental principles underlying the electrical precipitation process will be of much assistance in understanding the operation of the plant. A body highly charged with electricity, if of small enough diameter, or with sharp points, discharges electricity silently through the surrounding air. The corona discharge surrounding high tension lines under certain conditions,

COPPER CONVERTERS IN REFINERY BUILDING

B. & W. BOILERS SUSPENDED BUNKER, AND CHAIN GRATE STOKER

and visible as a pale light, is an analogous condition. Some of the electrical energy thus discharged is imparted to any particles of matter in the immediate vicinity, and they in turn are transformed into charged bodies (positive or negative as the case may be). As bodies charged with electricity of the same sign repel each other, all such particles will, if free to move, be violently repelled from the fixed electrode or charged body, and will be attracted to a body of opposite polarity.

The essential elements in a precipitation plant then are a source of high potential direct current and the two electrodes of opposite polarity. One set known as the discharge electrodes, are of such form as will facilitate an electric discharge from their surface. This is accomplished by making them in the form of a wire or light chain or a strip of metal having relatively sharp edges. The other set of electrodes known as the collecting electrodes, are of such shape as to prevent as far as possible any discharge from their surfaces, in this case, in the form of a pipe with a smooth bore.

These electrodes are so arranged in the precipitator that the different types oppose each other, and between them a silent or glow discharge is maintained by supplying to the discharge, electrode energy of a unidirectional character. The collecting electrodes are grounded for safety, the ground being used as the return circuit.

In this refinery the fumes from the copper converters are collected by hoods and carried away in two collecting flues, which unite at the base of the stack. These flues are of concrete and steel construction and are lined with brick. The gases on the way to the stack pass through the precipitating tubes which are arranged in two separate groups, one serving each flue, and all particles of suspended matter are driven to the enclosing walls and drop into suspended bins below, from which they are removed from time to time by means of the company's railroad.

Energy is supplied by means of seven 25 kw. motor generator sets of General Electric make. These motor generator sets take current from the d.c. busses and transform it into low-tension alternating current at sixty cycles. A step up transformer for each set serves to step the voltage up to 100,000 volts, at which potential the current is commutated and led to the precipitating tubes. The commutator is a bakelite disc about thirty inches in diameter and is keyed to the end of the motor-generator shaft, thus keeping it in exact synchronism with the alternator frequency; two metallic sectors are attached to the disc and the current is transformed into a uni-directional current by means of fixed sparking contacts, no mechanical connection being necessary.

From the precipitator the flue gases pass into the stack, which is 350 ft. high and 12 ft. internal diameter at the top. This stack, together with all others at the plant, is built of reinforced concrete, and was erected by the General Concrete Construction Co.

Air Supply

The converters and blast furnaces require a large volume of air, and for this purpose three high-pressure turbo-blowers are installed in a separate building. These blowers are made by the Ridgway Dynamo and Engine Co., and have each a capacity of 7,500 cubic feet of free air per minute, at 30 oz. pressure. The blowers are individually driven by high speed direct current motors at 3,600 revs. per min.

INTERIOR VIEW OF POWER HOUSE, SHOWING WEBSTER-LEA HEATER METER, INGERSOL-RAND COMPRESSOR, PUMPS FOR PLANT WATER SUPPLY AND TURBO-GENERATOR

EXTERIOR OF POWER HOUSE

Further refining of the nickel is done in the No. 2 building, and one of the most interesting features of this portion of the plant is the comprehensive arrangement of the mono-rail system. The bottom chords of the roof trusses have been designed to take care of the additional load, resulting from the mono-rail system and Shepard crane and hoist mono-rail trolleys serve every portion of the plant. Safety features, suspended walks and runways are provided, and it is impossible for any car to run off an open switch or otherwise do damage to itself or to another.

A stack of the same size and construction as that serving the No. 1 building serves to carry away and dissipate in the upper atmosphere all fumes from the roasting ovens here installed.

Power Plant

In common with the remainder of the refinery, the power plant shows evidence of careful planning and considerable attention to future conditions. The equipment at present installed is capable of taking care of a considerable extension to the plant, and ample space has been provided for future extension both of the boiler house and turbine room.

The building is of the usual brick, steel and reinforced concrete power house design, and the equipment has been arranged in an attractive layout.

The main power house boiler room contain four Babcock and Wilcox standard water-tube boilers, each of 4,319 square ft. heating surface, set in two batteries, These boilers are built for a working pressure of 160 pounds per square inch, each being fitted with B. & W. superheater, which superheats the steam about 100°. B. & W. chain grate stokers are also fitted.

Two B. & W. boilers of special design are also installed for utilizing the waste heat from the reverberatory furnaces of the nickel refinery. These boilers are designed for a capacity of approximately 400 boiler horse power each, and are of particular interest as they represent the latest design in waste heat boilers developed from very extensive investigation into this class of work by the Babcock and Wilcox Company.

Coal and Ash Handling

Coal is received from the cars in a track hopper crushed in a Jeffry single-crushing roll, elevated, and conveyed overhead to a suspended bunker, from which it is fed as required to the stokers.

The ashes are removed from the ash pits by ash cars running in an underground tunnel to the elevator and ash storage bin from which they are dumped into cars for removal.

One 6 ft. by 175 ft. reinforced concrete chimney conveys the products of combustion from the boilers in the power house. The waste heat boilers are served by two 5 ft. x 10 ft. reinforced concrete stacks.

Turbines and Generators

Two Ridgway-Rateau high pressure turbines furnish power for the direct connected d.c. generators, each of 1,000 kw. capacity. These turbines operate under 150 pound initial steam pressure, and 28 in. vacuum, and run at 1,700 revs. per min.

The power house also contains two other turbo-driven units, these being high pressure blowers supplying air for the converters. Like the turbo-generators, these units are of Ridgway-Rateau make. The turbo-blowers are each of 15,000 cub. ft. capacity, and deliver air at 15 pounds pressure. They are connected to high pressure condensing turbines operating at 8,500 revs. per min.

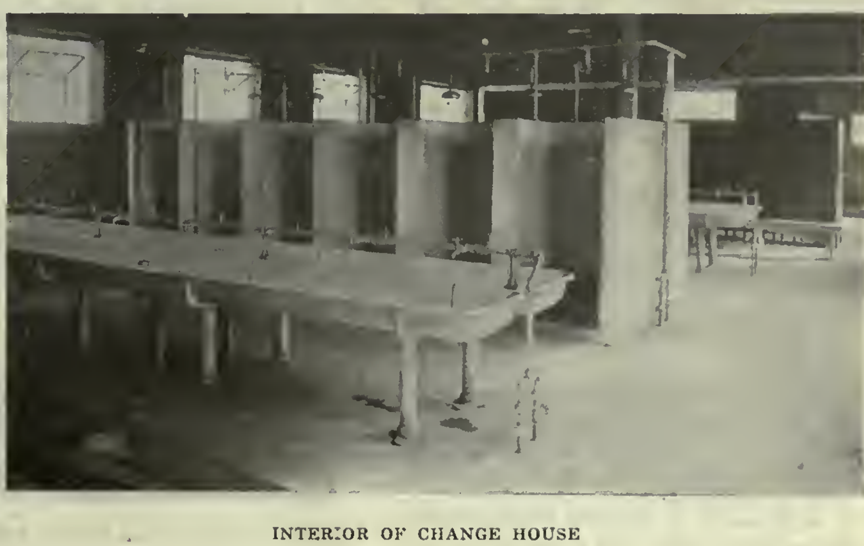
The superseding of the reciprocating engine by the turbine in the large power plants has provided the means for the elimination of the cumbersome blowing engine. The high rotating velocities obtainable to-day are especially well adaptable to the driving of centrifugal blowers, and the turbo-blowers at this plant are much more economical of space than blowing engines of similar capacity would be.

The impellers are built up around a large diameter shaft with dovetail radial slots milled in it. The impeller blades are tapered in section, being much thinner at the tip than at the root, and are driven into these slots, distance pieces being inserted between the blades in several stages. All turbines are equipped with Frahm tachometers, supplied by James Biddle, Philadelphia.

Condensing Equipment

Two No. 7 Westinghouse LeBlanc jet condensers, with individual air and circulating water pumps serve the turbo-generators. Each unit is fitted with a 31 h.p. steam turbine and reduction gear for pump drive. These condensers are each capable of handling 17,500 lbs. condensate per hour, and maintain a 29 in. vacuum, with 40° cooling water.

For the turbo-blowers two similar No. 5 units are installed. These are fitted with 21 h.p. steam turbines, and are capable of handling 11,000 lbs. of condensate per hour, at 29.05 in vacuum with 40° cooling water.



INTERIOR OF CHANGE HOUSE

Electrical Features

The main switchboard supplies the plant load with direct current at 250 volts, lighting and other 110-volt services being supplied by means of a three-wire service operated by two 20 kw. motor generator balancing sets. I. T. E. circuit breakers, Weston indicating ammeters, and Sangamo wattmeters are installed on the generator and feeder panels.

Feed Water Equipment

The feed water is heated by exhaust steam from the various plant auxiliaries in Webster-Lea heater meter units. The heaters were supplied by Warren Webster and Company, Camden, N.J., and the Lea meters by the Yarnall-Waring Co., Philadelphia.

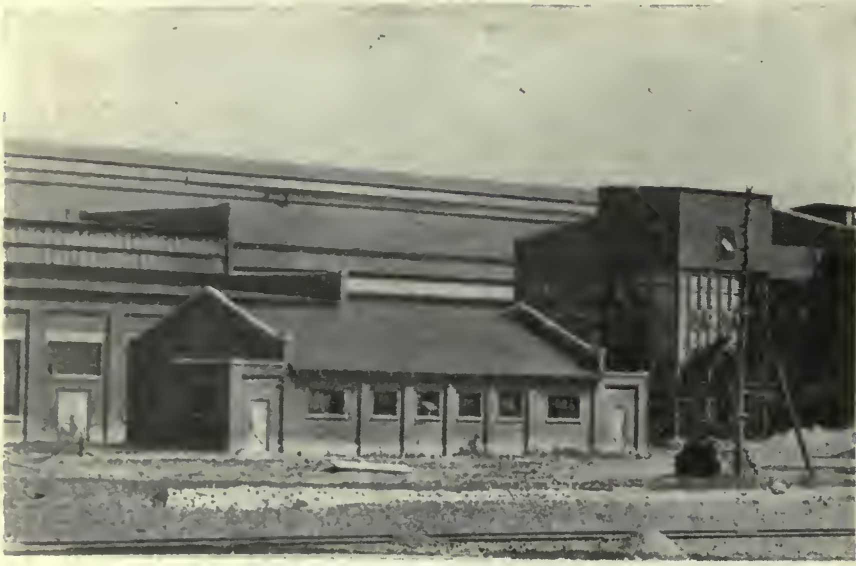
Two units were installed, one heater good for 5,000 h.p. equipped with Lea recorder, and having a capacity of 275,000 lbs. per hour, and another unit similar in construction to the first and having a capacity of 1,500 h.p., or 100,000 lbs. per hour. Both units are of extra heavy construction and were designed to withstand a back pressure of 10 lb. per sq. in.

A two-inch venturi meter meters all feed water, and the feed pumps are of Lea-Courteny make, direct-connected to Terry steam turbines of standard type. Owing to the horizontal parting of the casing, these turbines are very accessible for repair, and the fact that no oil comes in contact with the steam renders the use of an oil separator on the exhaust line to the heaters unnecessary.

Machine Shop

In a plant of this size facilities for the repairing of machinery are not only advisable but necessary, and ample provision has been made for this work in the machine shop forming a portion of the layout. The building is ample in size and has space to contain a large amount of equipment, and while the installation is not yet complete and while the machinery is not as yet installed in permanent position a very good idea of equipment may be gained from its enumeration.

A 12 and 28 in. McKabe double spindle lathe with a 24-ft. bed takes care of all the heavier turning required, while a Willard engine lathe serves for the finer and smaller repair jobs. A Hamilton drill is located adjacent to the lathes and a Niles-Bement-Pond radial drill is also installed. A Bertram double punch and shear, Kelley shaper and Racine hack saws also form part of the equipment. The machine shop building is about 175 ft. wide and about 200 ft. long with two side bays and center aisle for crane runway and also serves to house the forging equipment and a complete electrical repair shop. All repairing is done here and no work is sent outside, armatures and field coils are rewound and a stock of repair parts is kept on hand.



ONE OF THE SIX CHANGE HOUSES FOR EMPLOYEES

In addition to the machine shop a separate building houses a carpenter shop, which not only does any carpenter work required, but also serves as a cooperage in which all the stout barrels are assembled for shipping a portion of the company's product.

Sanitary Conditions

In a plant of this magnitude it is manifestly a wise thing to take provision for the workman's health and the sanitary features of the plant show a considerable amount of care and thoughtfulness in their working out.

All water used in the plant is chlorinated; this means not only drinking water, but every bit that is used in plant operations as well. The water supply is obtained through a four-foot square intake from the Welland Canal, is passed through the pumps, chlorinated and goes to an elevated tank, where time is given for its complete purification.

The company operate their own sewage system, all sewage being received by a sump, elevated by air ejector pumps and purified in activated sludge tanks located some distance from the buildings on an elevated piece of land.

To workmen engaged in laborious occupations provision must be made for the changing of wet and dirty clothing and the donning of comfortable and warm clothes for street wear. To this end four change houses have been built with a total of 600 lockers, hot and cold showers and lavatory accommodation.

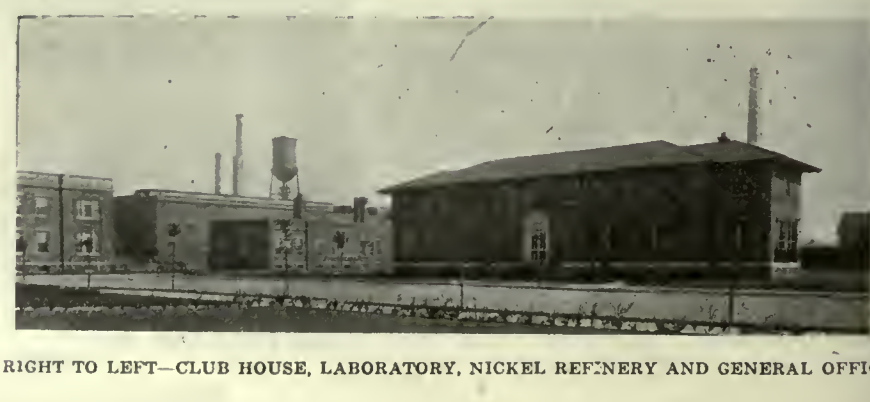
While the Port Colborne refinery is designed to have an initial output of about one-fourth that of the Bayonne plant, New Jersey, the present buildings have been constructed with a view to enlargement and it is probable that ultimately the entire output of the Sudbury mines will be brought to Port Colborne for refining. Future plans may also take into consideration the establishing of coke ovens. It is the opinion of the officials of the company that the nickel refining industry has come to Canada to stay, and while many obstacles have been encountered, many of them due to war conditions and labor scarcity, the industry is on a firm footing.

Production

While the refining of copper has been carried on for some time it has only been since the end of September that any shipments of nickel have been made. When the Canadian refinery is in full operation it is estimated that it will have a yearly production of 15,000,000 to 20,000,000 lbs. of nickel and 8,000,000 lbs. of copper.

The site of the refinery is large enough to permit of considerable extension, in all 350 acres, and the buildings are laid out in a manner that will readily facilitate such extensions as may be needed in future. The plant is estimated to cost approximately $5,000,000. Equipment and buildings alike have been chosen with a view to permanency, so although the initial charges are high, owing to war conditions, depreciation charges will be low in compensation.

All buildings are fireproof throughout, being constructed of brick, reinforced concrete and steel. The Foundation Company of New York and Montreal had charge of all work and were responsible for much of the design, in association with the company's own engineering staff.



RIGHT TO LEFT—CLUB HOUSE, LABORATORY, NICKEL REFINERY AND GENERAL OFFICE

Canadians Quick to Learn the Steel Business

Superintendent Had to Rely on Green Crew to Run His Plate Mill, But It Was Not Long Before Record Shipments Were Being Turned Out—A Good Source of Employment For Mechanics

By T. L. CROSSEN, Superintendent Plate Mill, Dominion Foundries and Steel, Hamilton

THE steel rolling industry in Canada, especially the rolling of plates and sheets, being a comparatively new industry here, and not well understood or appreciated by the average Canadian as a means for bettering the industrial conditions and labor markets of Canada, it might be in keeping with the reconstruction period of the present time, to point out some of the benefits to be derived from the steel rolling business and some of the things most desired and necessary in the way of organization and conditions to successfully operate a rolling mill.

The first thing necessary for the operation of a rolling mill, as well as any other business, is men. Men not of the ordinary slip-shod type, but men with determination and initiative, with the disposition to do a good day's work and expect a good day's pay for doing it—men who learn something each day from their work, and put it into operation in their next day's work, or in short, men upon whom you can depend.

There are so many good inducements for young men in the steel rolling industry that it is impossible for the writer to see any other line of employment that offers anything nearly so good. The work, while rather hard and exacting, possesses features which are found in few lines of work, and it has rather a gripping attitude from which a man never wants to get away, and the actual experience he gains is a stepping-stone for a splendid future.

T. L. CROSSEN,
Supt. Plate Mill, Dominion Foundries & Steel, Hamilton.

While the man of ordinary or practical education is always a valuable asset in a steel mill organization, and is able to command a much better wage than men of other trades, still the man with the technical and practical education is the fellow who goes to the top and stays there, and the young man who comes into a steel mill equipped with a good education and determination can't be stopped until he reaches the top. But you will find him as diligently studying his text books and trade papers as though he were still at school.

The Canadian seems to take to the steel rolling business as a "duck takes to water," and as an example of the fact, the following speaks for itself. The writer came to Canada some time back to install and operate a small steel plate mill, and before leaving the U.S.A. he rounded up a good operating organization and had everything shaped to bring them on just as soon as the plant was ready. In due course of time the mill was installed; he went back for his organization, when it was found that, owing to war conditions, it was impossible to bring but two men back, as some were already in the regulation uniform and the others being exempted from military service just so long as they stayed on their jobs, which was war work. There was just one thing left to do, that was to come back to Canada, break in a green set of men and get down to business. This was in the fall of 1917 and so well did these "Green Canadians" break in that by early spring they were turning out as much steel plate as most of the old organized mills across the line, and during the summer record shipments were made, which the writer believes have not been beaten by any one with a mill of the same type and size anywhere. These boys all had the necessary spunk to stick with the game until to-day they are capable of holding their own in any company, but one difference noticeable between the Canadian and the American workman in rolling mill practice is that the Canadian does not take his job quite so seriously as does his cousin on the other side, the result being that he doesn't report for work with the same regularity as does the American. But if the Canadian is given the chance to show in the steel industry he will send an industrial thrill throughout the world, because the kind of men that went up Vimy Ridge are not to be denied, and are perfectly capable of holding their own against any set of men on earth at any line of work to which they might turn.

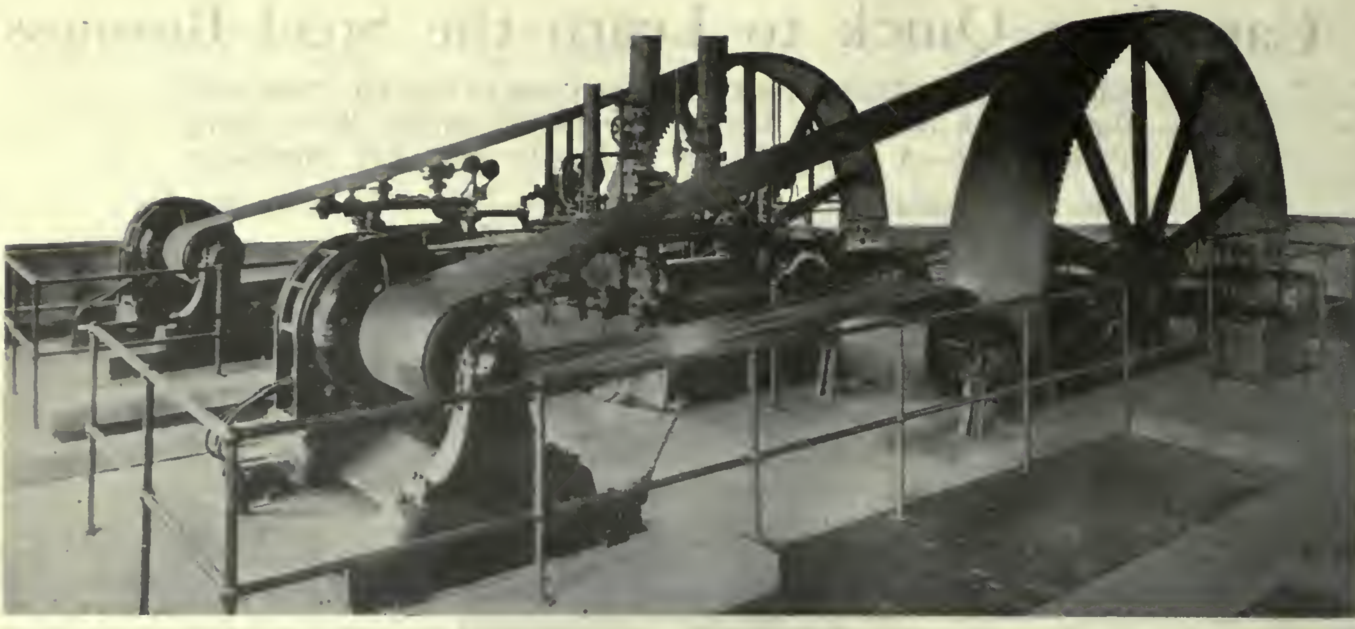
"What a man knows is a club for himself, and what he don't know is a meat axe for the other fellow," and the young man coming into a rolling mill equipped with a large-sized meat axe will be standing firm on his own job with his hands within speaking distance of the superintendent and looking square into the eyes of the manager, and his salary arm will soon grow long enough to reach quite a distance through the cashier's window.

In concluding, it might be well to say that so far as one is able to judge, there is no reason in the world why Canada is not sending finished rolled product to all corners of the earth, and if the Government at Ottawa will get back of the manufacturers in the way they should, we will see young Pittsburghs and Sheffields scattered throughout the Dominion, because the men, money and material are here.

Back in the 'Eighties the tin plate industry in the U.S.A. was nil, and every pound used was imported, mostly from Wales. The Government got busy in the matter, an investigation was made and the McKinley Protective Bill was passed and became a law, with the result that tin mills seemed to almost spring up over night throughout the country, and to-day the U.S. is one of the largest producers of tin plate in the world. What happened there can happen here, and right now is the time to make it happen.

The great Edison says: "All comes to him who hustles while he waits."

The development of the explosive and propellant industry in Canada has been an important achievement. It has been the policy of the Munitions Board to to establish national plants for the purpose of stimulating any important line of production which private enterprise was unwilling or unable to carry on, and seven of these plants, representing a capital investment of $15,000,000, were operated under the immediate direction of the board. The two largest manufactured explosives, and these, with privately owned plants, produced upwards of 100,000,000 pounds of high-grade explosives and propellants.



Effective Transmission Most Essential to Economy

Treatment of Shafting, Pulleys and Belting is All-Important—Various Details of Designs and Installations, as Well as Operating Features—Care of Belting and Proper Application of Dressing

By J. H. RODGERS

AMONG the many features involved in the problem of production few are more important than that of effective transmission of power from the primary unit to the machine that is performing the work. Very frequently, output is restricted owing to the failure of some part of the power installation, or the neglect in correcting some fault after the same has become evident. Too much attention cannot be given to this essential feature of plant operation. The treatment accorded to shafting, pulleys and belting, should be considered one of the fundamental details upon which the efficiency of the shop is based. No plant can expect to maintain a high average of production unless the transmission is constantly kept in the best condition. To accomplish this it is very advisable—and in large factories almost essential—to place the maintenance of this branch of the work under the supervision of one experienced party, a man that can give his entire time to the work, and with assistants if necessary. Where every machine operator is permitted to repair his own belts, tighten or adjust pulleys, effective operation is a doubtful factor. While it may be true that some men are thoroughly familiar with the peculiar and ofttimes apparently insignificant features relative to belt repair and upkeep, it is nevertheless good practice to have the transmission maintenance in charge of a man or gang especially selected for the purpose. We say selected in preference to appointed, as it is particularly advisable that the men doing the work of installation or repair, should know why they are doing it as well as how they are doing it. The various conditions under which a belt man has to perform his duties enables him from experience to evolve ways and means to maintain the maximum efficiency from the belts and pulleys under his charge.

The compilation of the following article is the result of observation and experience in the use and abuse of transmission equipment, and is here set forth as an aid to those who have, or may have, to do with the installation and subsequent repair and maintenance of shafting, pulleys, belts and accessories. In the unit system of machine operation, where each tool is driven by its own individual motor, the installation of overhead shafting is seldom required, but where the group system is adopted it is invariably a necessity to have a line of shafting to distribute the power to the different machines located about the shop. In general practice of to-day the group drive is so proportioned that the use of long lengths of shafting is vir-

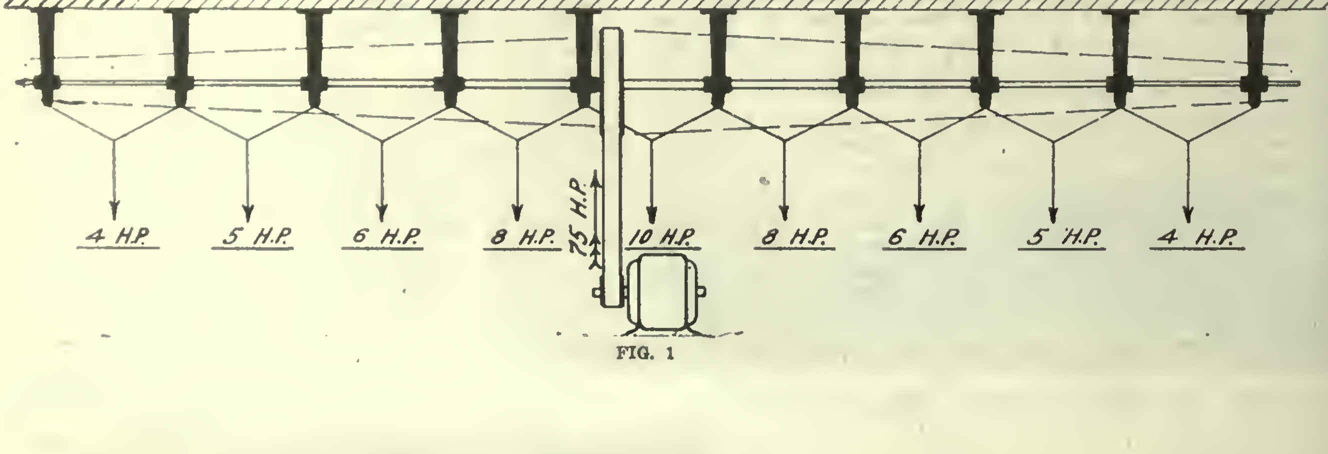


FIG. 1

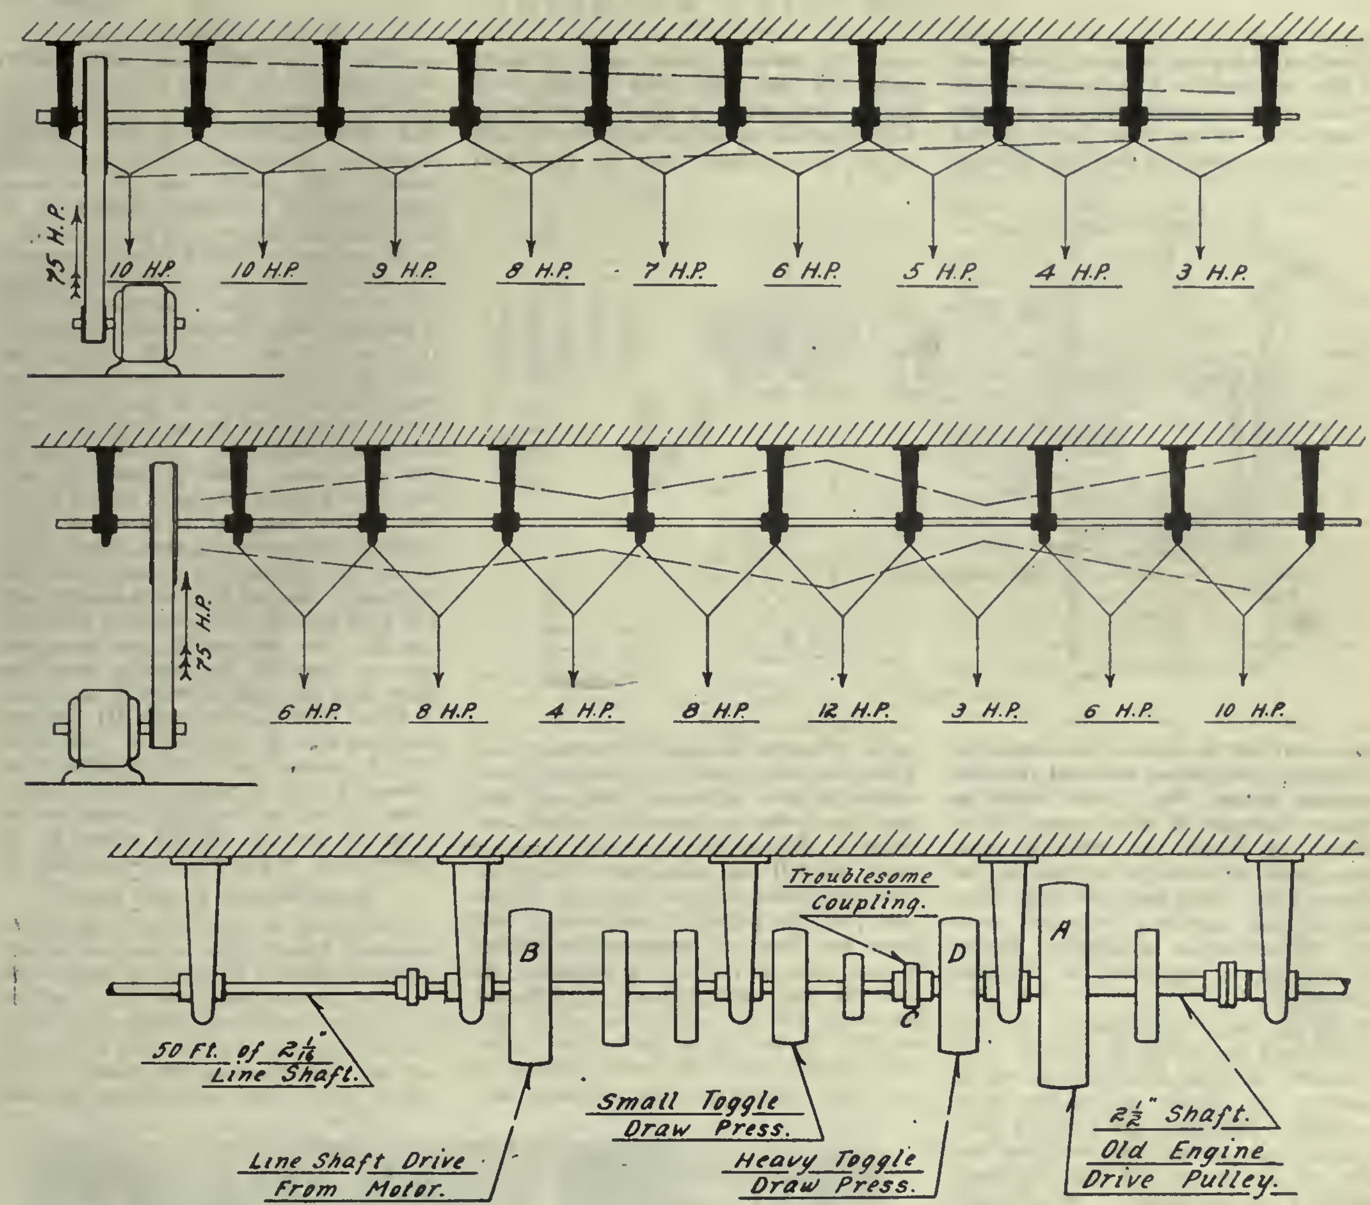

FIGURES 2, 3 AND 4

tually eliminated, and where main shafts of excessive length are used it is considered an economic feature to arrange the power distribution in such a way as to minimize the torque throughout the shaft. This twisting action may often be so great as to develop a grave source of annoyance and may eventually necessitate the rearrangement of the drive to overcome the trouble. Very frequently, an installation of machinery may be made in a plant, or additional units located in available space, with but little thought of the source or distribution of the power required to operate the different machine tools.

Minimizing the Shaft Torque.

In determining the position of the machines in a group, or when adding a tool to the existing equipment, the volume of power required to operate, and the special purpose of the machine, are two factors that should be given careful consideration. If this is not done the efficiency of the machine may fall below expectations, and be prematurely condemned. Wherever possible—and it is advisable in all cases—the heavier machines that require a proportionately high percentage of power for their operation, and particularly in cases where the consumption of power is spasmodically varied from light to heavy load, should be located as near the source of line shaft power as conditions will permit. While no fixed rule can be applied for installations of this character, owing to the fact that no two plants are identical in their layout or production requirements, a general recognition of stabilized distribution would meet the end desired in practically every instance.

It is seldom that the entire power developed by the engine or motor is consumed in the operation of the equipment, so that in initial installations allowance is always made for subsequent units to be operated from the primary line shaft. The character of the motor support is very important, but is dependable upon local conditions. Good results are obtained by locating the motor on the ceiling or on a specially constructed concrete base. The former practice provides more available floor space, but the latter assures a more stable foundation and more accessible for repairs. Where a support of this kind is not permissible, a substantial timber framework may be constructed to carry the motor, which may be located on the floor, wall or ceiling. The fundamental requirement. however, it to have the support rigid enough to eliminate all vibration, a condition that is invariably the progenitor of many motor troubles.

Location of Motor Drive

It is good practice to locate the driving motor about midway of the line shaft length, as illustrated in Fig. 1. When delivering to, or taking power from a line shaft, it is advisable to place the pulley as close to the hanger as possible, and this rule applies in particular to heavy drives or those where the absorption of power is intermittent, such as the operation of machines requiring a flywheel for stability, as in power presses, punching and shearing machines, and like equipment. In placing machinery in a shop it should be the practice to locate the heavy tools close to the main drive so that the twisting moment

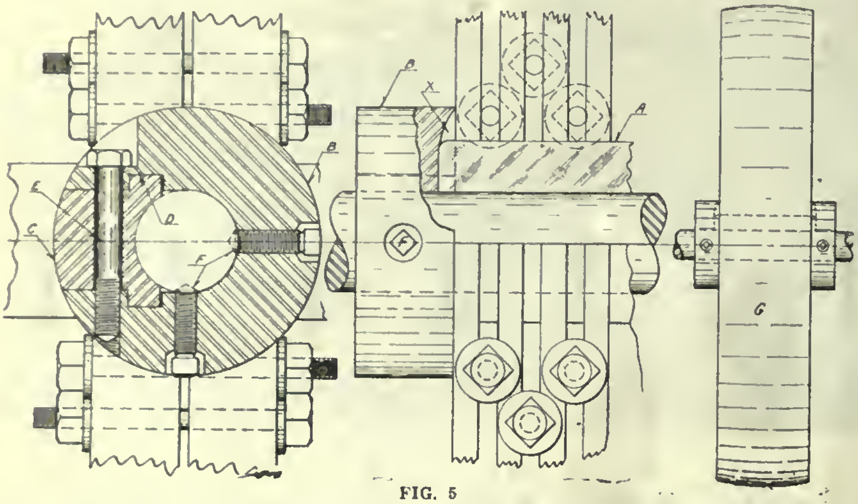

FIG. 5

in the shaft will be kept at the minimum, the lightest tools being situated farthest from the motor. Fig. 1 will serve as a good example of the central drive method; this shows the reducing value of the power delivered when nearing the extreme ends. This, however, is an ideal condition and can only be taken as a guide for an actual installation, theory only serving as an assist to practical adaptability.

When the drive is located at one end of the shaft, as shown in Fig. 2, it is imperative that the heavy machines be placed at the motor end of the shop. The farther such tools are situated from the motor the greater the twisting moment of the shaft and the increased possibility of line shaft. When main shafts are of extreme length it would be well to adopt a reducing size of shaft to aid in overcoming the shaft torque. An example of a line shaft drive that should be avoided is shown in Fig. 3. Here the drive is on the end, the diameter of the shaft uniform throughout its entire length, and the power delivered very irregular, factors that would provide excellent opportunities for inefficient operation. The skeleton lines show the varied fluctuations in the power delivered, and the great possibility of troublesome torque is quite obvious.

Inefficient Installation.

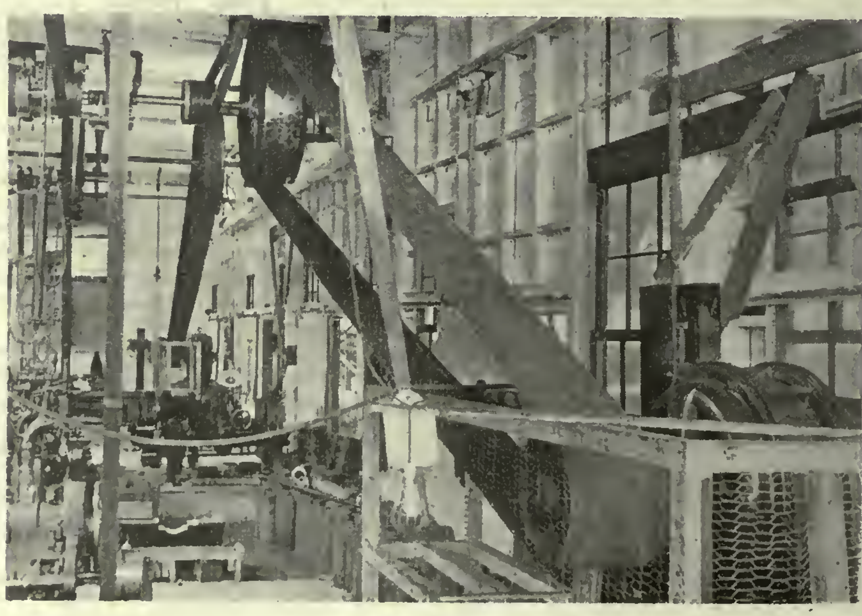
A special instance of ineffective line shaft drive is diagramatically illustrated in Fig. 4. In prehistoric days this shaft was driven by a steam unit belted to the large 6 foot cast iron pulley A, keyed to the length of 2½ inch shaft. The advent of the motor placed the engine in the discard and the new source of power was at the pulley B, the size of the entire line shaft, apart from the length above mentioned, being 2 1-16 inches in diameter. To the left of the drive, pulley B was approximately 50 feet of shafting carrying pulleys for operating various presses and other small tools. To the right was a couple of punch presses and a small draw press. Adjoining the reduction coupling C, and on the larger shaft, was the four foot pulley drive for the heavy drawing press. When the latter was in operation, more especially when on heavy drawn work, the coupling C was a source of constant annoyance, giving out a continual squeak when the full load came upon the press. This particular trouble was laid to the fact that the pulley A was out of balance and had an apparent oscillating motion, due to its poor alignment. Its removal was contemplated on different occasions, but no determined effort was made to do so. It is the writer's opinion, however, that the primary cause of the shaft trouble was the inefficient method of the drive itself, and the location of the heavy draw press in relation to the motor drive.

Cure for Slipping Pulley

In addition to the trouble arising in the coupling C, the pulley D, that operated the large draw press, could not be kept tight on the shaft and would persist in slipping when the extreme load came upon the press; this slip was invariably accompanied by the usual squeak. This pulley was of the wood split type but persistent tightening of the clamping bolts was of no avail. Sand paper and emery cloth was tried between the bushings but only provided a temporary relief. Holes. one-quarter inch in diameter were then drilled in the shaft at either side of the pulley and in line, and a 3/16 inch strip of steel placed between the two halves of the pulley, this being the available space after the clamp bolts were tightened. On either end of this strip was a short tit about ⅜ inch long, that entered the holes drilled in the shaft. The clamp bolts were used as a backing to support the steel strip. This served the purpose for a short time but eventually the end tits were sheared off. The final and effective repair is shown in Fig. 5. Two collars B were provided, open on the side for placing over the shaft, and the gaps filled with the piece C, fitted with the tee slots D; the two parts secured by the bolt E. The steel strip A, located as in the previous case, entered a slot X milled in each collar. When in position the collars were secured to the shaft by the set screws F. A general view of the repair is shown at G.

Belts Require Proper Care

Few details in connection with manufacturing receive less considerate attention than that of the belting that transfers the power from the line shaft to the various machines. Many men think that all that is required is a tight belt and all their troubles are over. If the belt is slack, take a piece out and relace the belt. Very good, if this is done with a knowledge of the necessary requirements. Few men will deny the advantages accruing from a well spliced endless belt, but how many of such belts will one see in the average shop, apart



MAIN DRIVE WELL PROTECTED BY GUARD

from those used on the main drives. The general practice on the larger volume of belts used is to cut the belts to the desired length and join by means of lacing or other fasteners. Many types of fasteners are now in use and are giving very satisfactory results, but few will retain the all-round efficiency of the ordinary leather lace when the joint is well made. One great disadvantage of metal fasteners, particularly where shifting of the belt is to be made by hand, is the danger to the operator contingent to the loose end of wire or metal portion. However, where careful attention is paid to such joints they are very effective for continuous drives. Leather lacing, nevertheless, will doubtless continue to be the general practice for belt repairs, owing to its accepted simplicity and general convenience.

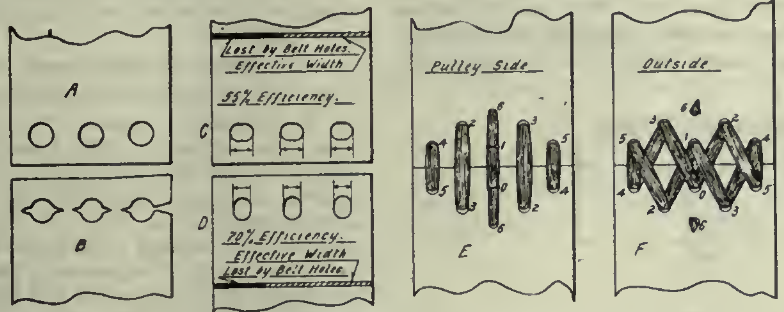


FIG. 6

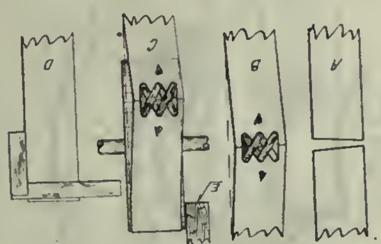

FIG. 7

Use Small Lace Holes

It must not be taken for granted, however, that all one has to do is to cut off a piece, punch a few holes and secure again with a lace, to obtain an effective drive. The fundamental details of a properly made joint may often seem of little import, but the subsequent operation of the belt may depend, very largely, on the consideration given to these apparently insignificant matters. When making a repair to a belt the beginner will usually make the lace holes of large size as indicated at A, Fig. 6. The inevitable consequence of such practice will be that shown below at B. With very few exceptions a belt will tear across the lace holes and seldom will fail in a direction parallel to the belt length. For this reason it is imperative that the amount of the leather cut out be kept as low as possible, consistent with the size of the belt and the thickness and width of the lace. Where it is necessary to enlarge the holes it should be done as shown at D and not as at C. This is obvious when comparing the resultant efficiency of the belt in each case. The heavy black line indicates the portion of the width cut away by the holes and the shaded line the effective section of the belt. With the same opening for the lace the efficiency of the lower method is 15 per cent. over that of the upper.

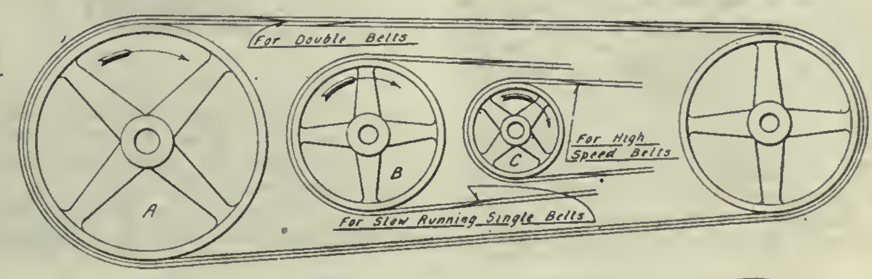
The best side of the belt to run upon the pulley appears to be a debatable question, as many favor the hair or smooth side, while others prefer the reverse. However, as the efficiency of a belt drive relies on the frictional contact between the surfaces it would seem practical that the smooth side would have the preference. Another factor in its favor is that of the recognized fact that the portion of the belt best suited for tensile strength is near the flesh or rough side, and the hardest side best adapted for the compression action; these features being quite evident when belts are operating on small pulleys.

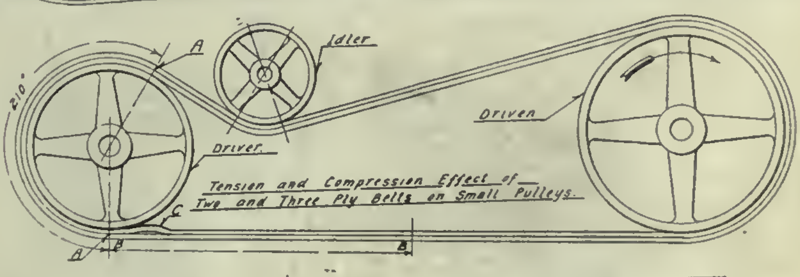
Making a Laced Joint

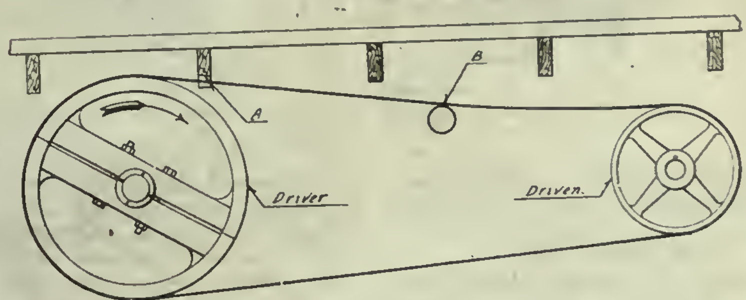
In making a joint it is advisable to use a thin lace in preference to a thick one. This coincides with what has been said on belt contact, as it is clear that the thicker a lace is the less will the contact be when the joint is passing around the pulley, and in addition the jar will be all the more pronounced. When making a joint the straight lacing should be made on the pulley side. Owing to the different widths of belts no fixed rule can be applied for lacing, but in general the method may be the same for every case. Holes should not be closer to the edge or end than one-half inch, with centre holes spaced accordingly. The best practice is to commence at the centre and work out and back on each side. As a guide the illustration at E and F is given. Starting at 0 and 1 the order is as follows: 2, 3, 4, 5, 4, 3, 2, 1 or 0, both sides of the centre being identical; the locking is performed by passing the free end through a small hole 6, and cutting a short slit to form a hook that will prevent the lace from coming out. This lock should be on the outside of the belt. After the joint is made it may be lightly hammered down with a wooden mallet.

Preparing Belt for Lacing

One of the essential factors of a belt joint is that the ends should be perfectly square with the run of the belt, to assure its smooth running. When cutting a belt the use of a try square, as shown at D, Fig. 7, is always advisable. Without such a tool the tendency is to make an angular cut as at A, so that when the joint is made it has the appearance as illustrated at B. When passing over a pulley the belt develops a tendency to oscillate, and such a condition is very much aggravated when the belt is running a little loose. To prevent it jumping off, a stick







FIGS. 8, 9 AND 10

is frequently secured to some rigid support and extended down at the side of the pulley, as at E. This, however, provides only a temporary remedy for a previous fault, as the weakest portion of the belt—the laced joint—is continually brought into violent contact with this "guide," and eventually the value

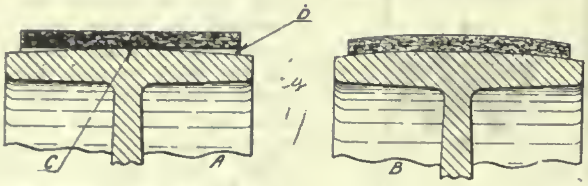


FIG. 11

of the joint is destroyed. Where guides are considered necessary—and they are only required to correct faulty installation or repair—they should take the form of rollers and not as rigid members; this would minimize but not entirely eliminate the source of trouble.

Direction of Travel

Another point that comes under discussion in connection with leather belts is that of the spliced joints, and their relation to the direction of travel. It is quite evident that the thin edge of the lap may show signs of parting after a period of service. For this reason some men contend that the belt should be run with the splice as shown at B, Fig. 8. On this principle the action of the pulley will aid in keeping the thin edge down to its place. On the other hand, some belt men say that the action of the air on the belt surface when in motion tends to lift the edge from its place. As this air action is greatest when the joint is passing around the pulley it would appear that the subject is open to discussion. However, as slow running belts are not subjected to excessive air action it might be said that the method shown at B would be best, and that at C best suited for high speed belts. Irrespective of the advantages claimed for either method, the entire question seems to be one of careful attention in the matter of repairs and maintenance so that faults may be remedied as soon as they are observed.

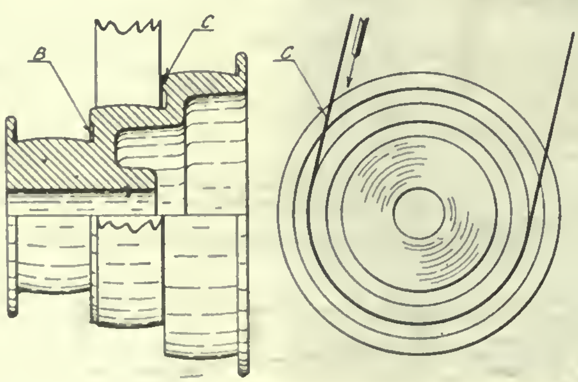

FIG. 12

Avoid Small Pulleys

In double or three ply belts these splices can be run to meet both conditions as shown at A. In the use of double or triple belts for heavy power drives, care should be taken to use pulleys as large as possible, consistent with speed requirements, as effective heavy drivers are not to impossible on pulleys of small diameter. This is quite clear when we consider the lack of flexibility of the heavier belts. Another argument against the use of small pulleys is the imperceptible cheeping action of the belt in making the round of the small pulley. It will be obvious to all that two opposite forces are at work when the belt is on the pulley—that of compression on the inner side and tension on the outside. These forces are neutralized between the curves, but immediately come into action again when the pulley is reached. For instance, suppose the length B-B, Fig. 9, to represent the length of the pulley circumference in contact with the belt. The length of both sides of the belt between B-B will be the same, but not so when this same portion is wrapped about the pulley, as at A-A. If the contraction of the inner side equals the expansion on the outside, the centre length will remain unchanged, but such is seldom the case, so that the tendency is usually to destroy the adhesion of the two layers as shown at C. For this reason too small pulleys should be avoided when using double or three ply belts.

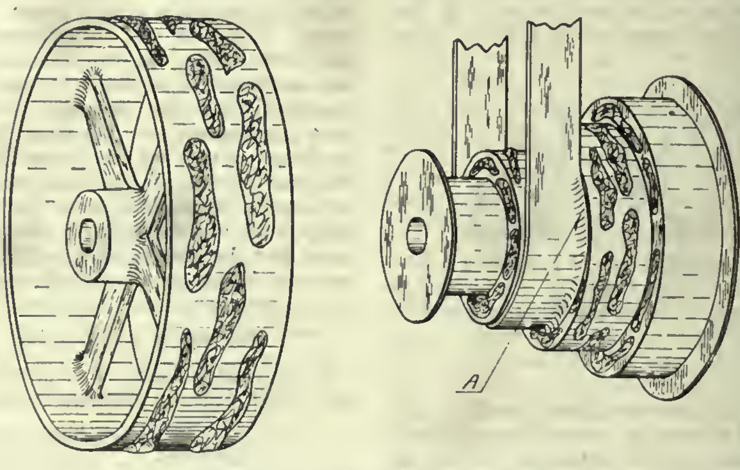

FIG. 13

Idlers as Tighteners

The use of idlers is often resorted to, but for the above reason, it is well to have these of fairly large diameter, especially where the idler contact is excessive, as the forces at work are directly opposed to those on the main pulleys, thus creating a destructive bending action in the fibres of the belt. For belt drives of this character it is advisable to maintain flexibility by means of some liquid preparation that will penetrate the fibres of the belt. When idlers are used they are invariably located close to the smaller pulley, so as to increase the arc of contact and likewise the driving power.

Keep Pull on Under Side

In the installation of horizontal or oblique drives it is always advisable to locate the shafting so that the pull on the belt will be on the lower side. This will bring any slack on the upper portion of the belt and the sag will add to the lap on the pulleys. To the average

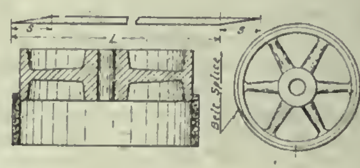

FIG. 14

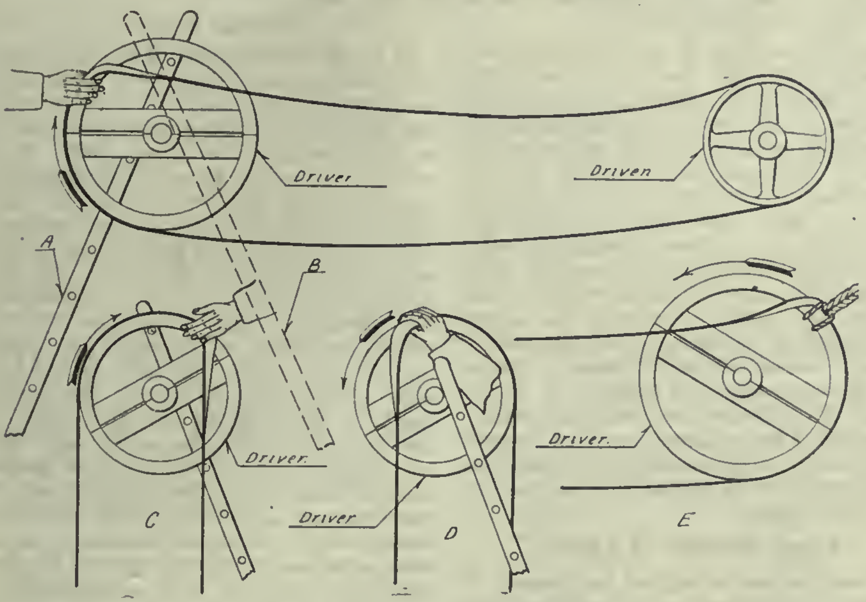
man a tight belt is supposed to deliver the greatest power, and while in some respects this may be true, much of the power delivered is absorbed by the additional friction on the shaft bearings, so that the effective pull may be less than would have been the case with a little slacker belt. When the centre distance of a drive is relatively short it may be necessary to operate with a fairly tight belt, but in a long stretch a slack belt will give equal, if not better service than a belt that has excessive initial tension.

Have Plenty of Clearance

In many shops particularly those with low ceilings, the shafting may be placed in such a position that belts on large pulleys have very little clearance; in some instances it is necessary to cut a piece out of a beam or joist to allow the belt to operate. Frequently, this cutting is just sufficient to clear the belt, as



shown at A in Fig. 10. When the drive is one of a fairly steady or uniform load this may be ample, but if the load on the belt shows a tendency to fluctuate it is more than likely that the belt will flop up and down, invariably resulting in the belt striking the joist. Such action is very detrimental to the life of the belt and especially the lace at the joint, as the rubbing will soon effect its destruction and repairs are required. This also applies to other possible points of interference, as pipes or rods passing either above or below the belt, as shown at B. Where points of interference are a source of annoyance, facilities should be provided to minimize the trouble, such as the giving of greater clearance, or the placing of rollers to prevent excessive wear on the belt or laces.

Crowning of Pulleys Important

Steady running of belt is essential to effective transmission. For continuous drives, belts are generally run on pulleys that are very little wider than the belt, and to maintain its position in the centre, the pulleys are invariably crowned. This crowning usually consists of two straight tapers meeting at the centre of the pulley face. The amount of the taper varies from ⅛ inch to ¼ inch per foot; that is, a pulley 12 inches wide would be about 1-16 inch larger in diameter in the centre than it would be at either edge. In a straight taper crown, however, it will be seen that the apex C, Fig. 11, forms a definite or pronounced breaking point; nothing very serious possibly, but with a tendency, especially in new and heavy belts, to provide an air space at the edges D. A better plan of pulley crowning is that shown at B, where the surface forms an arc; this method equalizes the bending stresses throughout the width of the belt and makes the surface contact more uniform.

Careful Use of Belt Dressing

To increase the driving power of a belt, or rather to increase the pull, the use of belt dressing is very frequently adopted, and when judiciously applied such dressing may add materially to the effective operation of the belt, but where careless or thoughtless application is made, the practice may not only prove inefficient but very destructive to the belt. The driving power of a belt depends upon its flexibility and adhesive qualities, therefore the object of a belt dressing must be such as to retain these essential features. The adhesive action may be increased by careful application of belt dressing, but pliability can only be attained by a liquid or semi-liquid preparation that will penetrate the pores of the belt. When properly used a surface dressing will very often pull one out of a hole, but if constant applications are required to maintain the "pull," steps should be immediately taken to eliminate this apparent necessity, which is generally nothing but neglect in maintaining the belts or pulleys in good working conditions.

Destructive Practice

Where the surface dressing—or as it is often called, the "belt stick"—is freely used, it is not uncommon to see pulleys in the condition shown in Fig. 12, with large patches of the dressing clinging to the face. As said before a belt derives its power from frictional contact with the pulleys and while the pull from a well "dressed" belt may seem better, the general efficiency has not been increased. This may be made more clear when one realizes the air pockets that must be formed between the patches on the pulley surface shown in Fig. 12. To this must be added the pull required when the belt is leaving the pulley. A stamp may be easily placed on an envelope but some action is required in its removal. At your next opportunity notice a drive of this description and listen to the noise when starting or stopping. Just like pulling a porous plaster from your back.

However, where the excessive and needless use of belt dressing is more pronounced is on cone pulleys, where belts are required to be changed from one speed to another. The action of the latter is very similar to that of the straight pulley, but where the greatest trouble is caused is on the flange or shoulder. The accumulation of the dressing at this portion soon attracts the edges of the belt, with the result that it shows a marked tendency to climb to the next higher step, and very often succeeds, the inevitable consequence being a broken belt or lace, generally the latter. At other times the belt may climb, but instead of taking the next step will flop or twist completely over, once or perhaps twice. The writer has seen this happen on several occasions. These conditions should not be allowed to continue, and pulleys should be scraped clean as soon as possible. Even without the presence of dressing, belts on cone pulleys may often show an inclination to climb, due to faulty belt or pulley alignment. To assist in the proper running of the belt the flanges or shoulders should be undercut as shown in Fig. 13 at B. This provides a point of contact for the belt at C, the edge being kept clear of the flange throughout the entire wrap of the pulley.

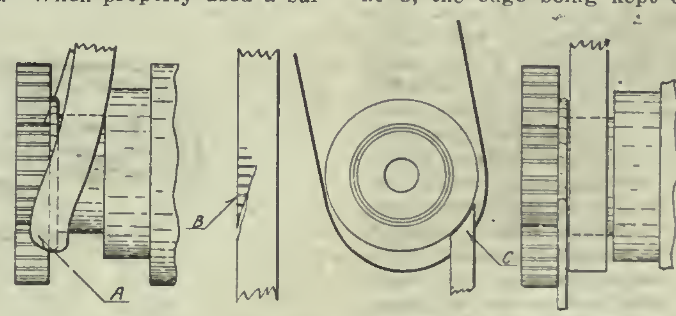


FIG. 16

Covering a Pulley With Leather

Many men resort to the practice of covering pulleys with leather to increase the adhesive power of the belt. When doing this the method generally adopted is to form an endless belt by means of splicing. First cut a piece of belting the required width to a length L, equal to about ⅛ inch per foot less than the circumference of the pulley; connect the splice in the usual manner, and when set, place the ring over the pulley, starting it evenly all round. Coat both the inner surface of the belt and the outer face of the pulley with hot glue, then take the pulley up by the spokes and carefully work the leather ring into place by

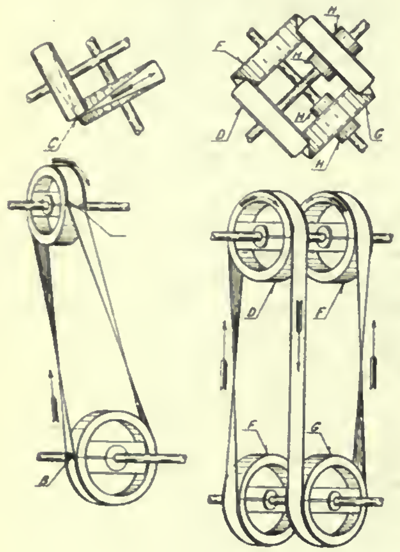

FIG. 17

bumping the edge on the floor or surface plate. Do this gradually to avoid kinking the leather, and quickly to prevent the glue from premature setting. If deemed advisable, a few copper rivets may be used.

Faulty Use of Nails

A leather-covered wooden pulley that came to the notice of the writer some few years ago was quite interesting and bears description. This pulley was located on the extreme end of a line shaft and was utilized to drive the countershaft of a buffing machine situated on the floor above. The buffer was subjected to very heavy service, frequently almost stopping at times, causing the belts to slip. Upon one occasion the writer was called upon to repair the main drive belt. Upon investigation it was found that the main drive was in a very dark storage room and the belt could only be seen by means of a special light taken to the ceiling. As stated, the pulley was found to be covered with leather, but a glance at the belt showed a strip right through the center on the inner side, that was in a deplorable state. Looking to the pulley for a cause it was discovered that the leather covering had been put on with nails, and several of these were protruding from ⅛ to ¼ of an inch. In this particular instance the nails were removed and replaced by fine wood screws, which proved successful. Probably the man that first covered this pulley thought that the belt would do its own driving.

Throwing Belts on Pulleys

A feature of factory operation that involves considerable risk to the workman, yet one that will likely never be discontinued, is that of throwing belts off and on the pulleys while the same are in motion. If shafting had to be stopped or even slowed down every time a belt required to be placed on or removed from a pulley, the suspension of production would be almost prohibitive, therefore the danger incidental to the maintenance of belts will always be with us. For this reason we should adopt the safest means of carrying out the work.

In the throwing off of a belt the risk is lessened by the fact that the belt comes off of its own accord in the greater number of cases, owing to slackness, poor alignment, broken lace, or one of many causes. When a belt requires to be thrown off a suitable stick is invariably used, but care must be exercised in its manipulation. Pressure should be applied at the leading side of the belt, that is, the side that is passing "on" to the pulley, and it should be seen that sufficient space is available at the side of the pulley to take the belt without it interfering with adjoining pulleys or couplings. If belts are thrown off regularly, other than for repairs, provision should be made to carry the weight of the belt so that it will not rest on the constantly-revolving shaft.

Proper Position of Ladder

When placing a belt on the pulleys it should first be located on the "dead" or driven pulley, as shown in Fig. 15, the actual running on of the belt being done on the driving pulley. As the latter is usually on the main shaft, in the majority of cases a ladder is necessary, and in placing the ladder, care should be taken to locate it on the outside of the drive, as shown at A. With the exception of special cases, where the drive shaft is located along a wall, the ladder should never be placed in the position B, and when such is absolutely necessary the shaft should be stopped and the belt run on at a very slow starting speed.

When standing on a ladder for this work the body should not be in a strained position, and one hand should be placed on a fixed object for support. For the lighter sizes of belts it is seldom that the speed of the driving shaft is reduced, as the knack is soon acquired of running the belt on. On the heavier belts the work is more difficult, but dexterity is attained with practice. When the belts are very heavy or extra tight, or with a load on the belt, "snapping on" is not so easy, and slipping of the belt is often necessary, while speed is accelerating. Under these conditions, however, care must be taken that the belt does not run off the driven pulley. On narrow pulleys there is always the possibility of the belt jumping off on the opposite side. Where possible, a good method is to place the ladder close to and on the opposite side, as at A, so that the lower edge bears against the pulley and acts as a guide for the belt.

Vertical Drives

If the belt is too tight or too heavy for the hand method, that shown at E may be adopted. By means of a light rope the belt is locked to the pulley and drawn on by slowly revolving the shaft. For vertical drives the same precautions are required. The correct method is that shown at C, where the belt is gathered up and placed on the far side of the pulley and drawn around to the near side, the ladder being placed as shown. A dangerous practice is that illustrated at D, where the belt is placed at the near side and followed on by the hand to the far side. This brings the arm in close proximity to the shaft at the final jerk of the belt as it takes the pulley, with the accompanying risk. When it is necessary to place the ladder in this position the workman should stand well up on the ladder, and it is also advisable to slow down the speed of the shaft. In the handling of belts, due consideration should be given to the surrounding conditions and at all times lean to the side of "Safety First."

Lathe Belt in Back Gear

A not uncommon occurrence in the operation of a lathe where the workman is not conversant with the proper knack, is that of the lathe drive belt jumping over the back cone flange and getting caught in the teeth of the gears, as indicated at A, Fig. 16. After this has happened the belt will have an appearance something like that at B. Where there is a danger of a belt running into gear trains, guards should be placed in suitable positions to protect the belt, as nothing will destroy a belt quicker than mangling it in the teeth of gears. For protecting a lathe belt a simple guard made of sheet steel, proves very efficient.

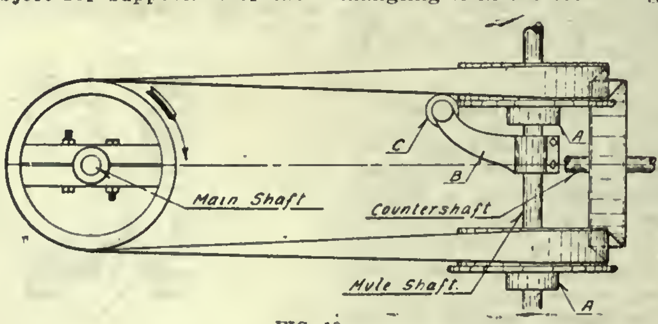

FIG. 18

Installing a Quarter Turn Drive

Drives other than those connecting parallel shafts are occasionally required, and local conditions must govern their installation, as a specific method is generally necessary for each individual installation. The most common is that of the quarter turn drive, and it may be accomplished in a variety of ways. The simplest form is that illustrated at the left of Fig. 17, where the shafts are placed at right angles, with the pulleys properly lined. The fundamental requirements in a drive of this character is that the points A, B, where the belt leaves the pulley, will be on the same vertical line as indicated at C. This is essential, otherwise the belt will not remain on the pulleys without the use of guides. One great objection to the two-pulley quarter turn drive is the fibre stress resulting in the angle of the belt in leaving the pulley. This fault is less pronounced if the shaft centers are relatively far apart.

A better form of quarter turn drive, but one that requires four pulleys and about twice as much belt, is shown to the right of Fig. 17. In this case one of the pulleys on each shaft must necessarily be a loose pulley, running in the opposite direction to its mate and kept in alignment by the collars H. The unavoidable quarter twist is required in the belt, but the fibre strains are less pronounced. With this method the belt can be run in either direction, whereas that shown at the left can only be run in the direction indicated by the arrows.

The Mule Drive

Another drive that is occasionally used is that illustrated in Fig. 18. This is known as the mule drive and is adopted where a machine is to be operated at right angles to the line shaft and where a quarter turn drive is not permissible. In the mule drive the connected shafts usually lie in the same horizontal plane, invariably at right angles, where the prolongation of the counter shaft would intersect the main shaft. The intermediate pulleys revolve in a horizontal direction on a vertical shaft. When it is desired to run the belt in either direction it is advisable to have the two main pulleys of the same diameter. Collars are necessary on the vertical shaft to support the pulleys. One bad feature in a mule drive, where the load is a fluctuating one, is the tendency of the belt to run off the mule on the slack side. It is preferable to have the pull come in the lower side, but in either case the slack side should be provided with a guide pulley C, carried in a bracket B fixed to the mule shaft. This will aid in supporting the belt when the load is on the machine.

SHIPBUILDING FIGURES

In the shipbuilding return issued last week by the Secretary to the Admiralty, the output of merchant tonnage in the United Kingdom and Allied and neutral countries during the years 1915, 1916, 1917, and the quarters ended March 31, June 30, and Sept. 30, 1918, was set out as follows:

Period.	United Kingdom. Gross Tons.	Allied and Neutral. Gross Tons.	World. Gross Tons.
1915......	650,919	551,081	1,202,000
1916......	541,552	1,146,448	1,688,000
1917......	1,163,474	1,774,312	2,937,786
1918			
1st Quarter.	320,280	550,037	870,317
2nd Quarter	442,966	800,308	1,243,274
3rd Quarter	411,395	*972,735	1,384,130

*Provisional figures.

The output for the world during the last quarter exceeded the losses from all causes by nearly half a million tons. The United Kingdom monthly figures were set out as below:

	Completions. 1917. Gross Tons.	Completions. 1918. Gross Tons.
January	48,089	58,568
February	79,451	100,038
March	118,699	161,674
April	69,711	111,533
May	69,773	197,274
June	109,847	134,159
July	83,073	141,948
August	102,060	124,675
September	63,150	144,772
October	148,309	136,100
Total, 10 months to Oct. 31, 1917....		892,162
Total, 12 months to Oct. 31, 1917....		1,045,036
Total, 10 months to Oct. 31, 1918....		1,310,741
Total, 12 months to Oct. 31, 1918....		1,582,053

As will be seen, the United Kingdom output for the three months ended Sept. 30 was 411,395 gross tons, a decrease of 31,571 gross tons as compared with the total for the second quarter. Allied and neutral countries produced, however, 972,735 gross tons (provisional figures) compared with 800,308 in the previous quarter. The output for the world was 1,384,130 gross tons—the highest record this year. The new merchant ship construction in the United Kingdom in October shows a falling off as compared with September of 8,672 gross tons, and is 12,209 gross tons less than the production of October, 1917. The total for 12 months to Oct. 31 last is 1,582,053, as against 1,045,036 for the similar period ended Oct. 31, 1917.

BLAST FURNACE BLOWER

In a blast furnace blowing set recently constructed by the British Thomson-Houston Company, of Rugby, the motive power for the blower, which is of their standard two-stage design with balanced impellers needing no balancing devices for end-thrust, is furnished normally by a synchronous motor running at 3,000 r.p.m.; but to guard against interruption of the blast through failure of the supply current or breakdown of the motor an alternative means of driving is provided in the shape of a Curtis steam turbine mounted on the same bedplate. This arrangement involves the insertion of clutches between the blower and the motor on one side and the turbine on the other, and the conditions laid down by the purchasers required the clutches so designed as to disengage the motor and engage the turbine automatically, in the absence of attendants, while the blower is running. In bringing the set up to speed the motor is started as a squirrel-cage induction motor, the clutch between it and the blower engaging as soon as its rotor begins to rèvolve. When the motor reaches practically synchronous speed, it is paralleled by closing the field switch of the motor rotor circuit, and it then works as a synchronous motor, at the same time acting as a power-factor adjustment on the 3,000 volt 50 cycle supply. On the steam supply main of the turbine there is a balanced starting valve which is kept closed by the delivery air pressure of the blower and the turbine is thus held out of action. But if the motor for any reason ceases to drive, the speed of the blower falls, the air delivery pressure is reduced, the starting valve of the turbine opens, the clutch between the turbine and blower shafts engages itself as soon as they reach the same speed, and the blower is driven by the turbine, the motor clutch automatically disengaging itself. A small drop in the air pressure suffices to open the steam valve of the turbine and the change-over takes place without shock; in fact, it is said to be almost impossible to detect the moment of engagement, although the speeding up of the turbine shaft and the slowing of the blower shaft are both extremely rapid. It is suggested that the type of clutch designed for this blowing set should find application, for example, under conditions where it is essential to maintain continuity of circulating water supply to the condensers of large turbo-generators, or where with motor-driven auxiliaries failure of current supply to the motors might cause serious temporary shut-down. The circulating pump would be provided with both a motor and a turbine, connected to it through clutches, and the turbine would be automatically started, when required, by means of a valve controlled by the pressure of the water delivered to the condenser.

TWO-CYCLE PARAFFIN ENGINE

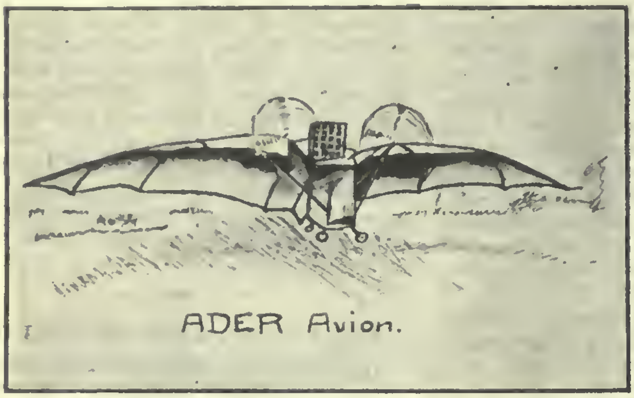
In accordance with the requirements of the Government Department, by which it was ordered, a 50-h.p. two-cycle internal combustion engine made at Eccles, Manchester, by the Record Engineering Company, of Donington House, Norfolk Street, W.C.2, was recently subjected to an endurance test of five days. During that time it ran continuously night and day at full load under paraffin, without attention or adjustment of any kind beyond the usual filling up of the fuel tanks and the supply of lubricating oil. None of the plugs were changed, and when the engine, which is of the V type, with four cylinders and two cranks, giving four impulses per revolution, was dismantled at the end of the test, it is stated that no appreciable signs of wear were visible, and that the cylinders were practically free from deposit. In the design adopted by the company, the two to one gears, with the camshafts, cams, tappets, and poppets found in the ordinary four-cycle engine, are eliminated and are replaced by a simple piston valve generally for each pair of cylinders, worked by an eccentric on the main shaft. As the valve merely controls the distribution of gaseous fuel to the pump cylinders it is not subject to a pressure exceeding a few pounds per sq. in., nor to the high temperatures of the working cylinders. The crank case is used only as a reservoir for lubricating oil and not for handling the fuel mixture, so that the deposition of carbon and soot on the bearing is avoided, as also is the mixture of fuel oil with the lubricating oil. As the cylinder heads are made loose, both piston tops and combustion chambers can be cleaned without dismantling.

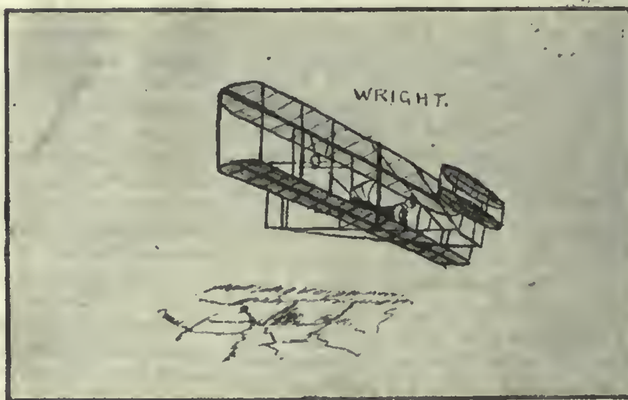
There's Nothing Impossible About Flying Now

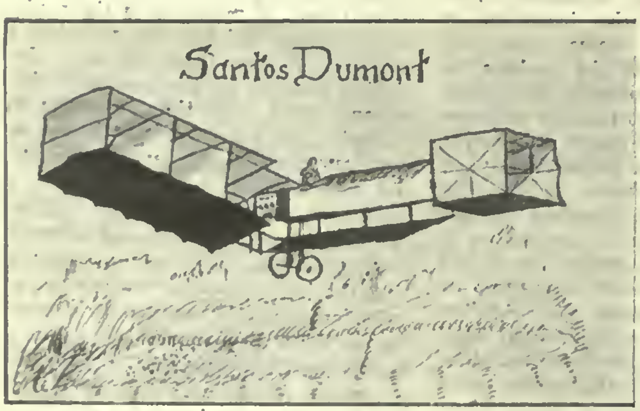
The Growth of Aviation Has Been Steady, But There Have Been Many Obstacles in the Way—A Resume of the Various Types of Machines Used in the Development of Flying From Its Infancy

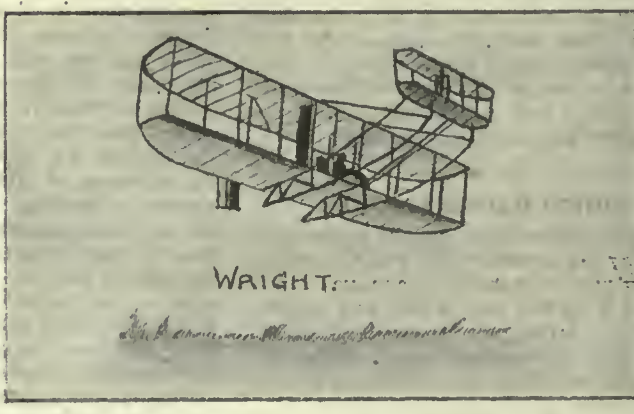
Written for Canadian Machinery by "ENERGY"

IT would be absurd for anyone to attempt to give a complete history of aviation. Is there one amongst us who could scour the world and find out every man who has experimented in aviation? There are, doubtless, thousands of unknown and unsung heroes who have passed into oblivion with their first attempts at flying and who, if the fates had allowed a second choice, would probably have turned the path of aviation into a totally different direction. The art of flying is now an ordinary accomplishment and within the reach of any sensible and average man of modern education. But it must not be thought by anyone that flying is of easy accomplishment. Just as there are drivers of automobiles who know nothing of their machines, beyond steering it along the roads, starting and stopping it, so there are pilots who can fly and fly only. Beyond this point they are useless. It is not so much to these men that the success of aviation is due. It is to our pioneers, such as Wright, Santos Dumont, Voisin, Farman, Curtis, Latham, Grahame-White, Cody, and scores of others that we owe the foundation of this new mode of transit. But it is not my object to dwell on flying itself, but rather to give a brief description of the evolution of our modern masters of the air.





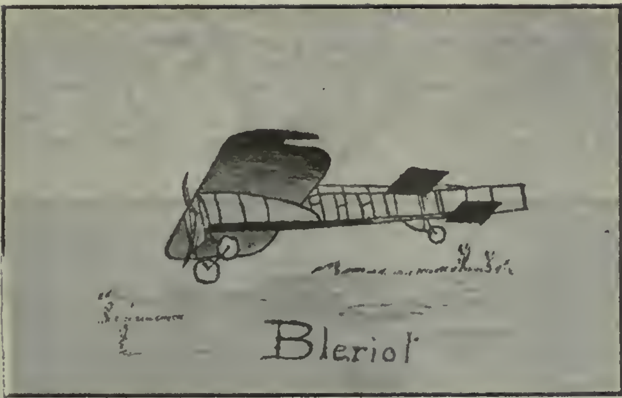




Started Twenty Years Ago.

The aeroplane is not by any means a very new thing, as we have records of flights being made over twenty years ago. In fact our very first authentic record of a flight was of that made in 1897, in an "Ader Avion" machine. It will be seen that efforts were made that the lines of this machine should resemble those of a huge bat. As one glances at the design of this early machine and compares it with the gracefulness of our latest aeroplanes, can one fail to recognize the immensity of the strides aviation has taken? Undoubtedly the war has hastened this perfection, though cynical people may ask why it has taken so many years to bring it to this state of perfection. My answer to them would be, that Rome was not built in a day, but only by ceaseless and untiring effort. The lack of interest and support on the part of the public greatly cramped our pioneers in the early stages. Now that this interest has been fully aroused aviation can go forward and who can forecast the climax of this latest science which is almost daily bringing forward some new discovery?

The world has much to be thankful for, for such experiments as were carried out in 1906-7-8 on Santos Dumont, Wright Bros., Voisin, Henri Farman, A. V. Roe (Avro), and Bleriot types of machines, which to our more trained eye look very crude and almost incapable of performing the wonders with which they are credited.

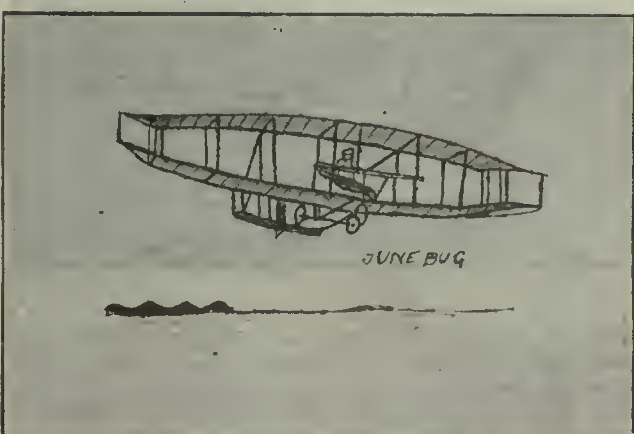


The Wright Bros.' First Machines

Taking a glance at the machine built by Wright Bros. in 1903, on which they made their first power flight, one can almost imagine the sensations the pilot must have felt as he glided through the air in his prone position and we cannot help feeling grateful for such a pioneer. I myself have descended in more than one steep nose-dive and retained a sitting posture, but what my sensations would have been whilst lying on my stomach with my head descending to the ground at an alarming rate I can only conjecture, but it would, I assure you, be a most uncomfortable feeling and require no ordinary amount of nerve. The Henri Farman was the first aeroplane to be used extensively, whilst the Avro was the first heavier than air flying machine built by British brains and labor to be successful. In 1907, the Wright Bros. modified their 1903 machine and fitted it with a 40 h.p. motor. On this machine much of the first real flying was done. The next two years saw some rapid advances made, because it was at this period popular interest had been aroused, the ever sceptical public being at last convinced that there were possibilities, money was advanced, competitions opened, trophies offered, and schools were formed to promote and develop this new idea, which was still thought by a great number of people to be a fool's pastime and a waste of money.

A Prize for Flying a Mile

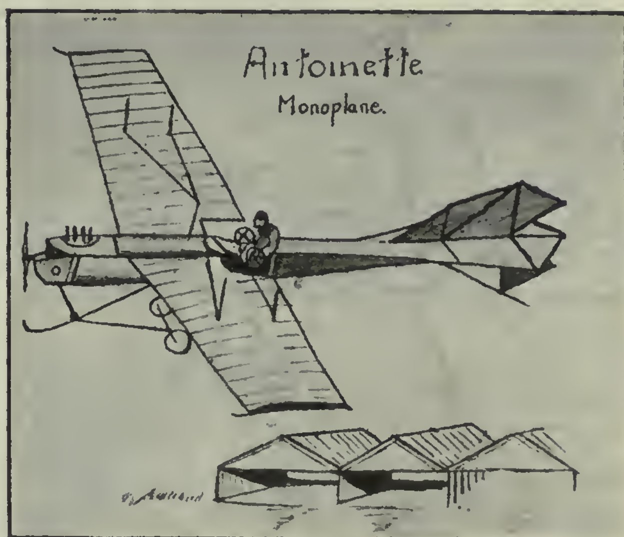
In 1909 we had the semi-Wright biplane, built by Short's, fitted only with a 35 h.p. engine on which Mr. Moore-Brabazon won the Daily *Mail* £1,000 prize for the first successful aviator to cover a mile circuit on a British aeroplane. (Think of it, one mile! and to-day we laugh at flying hundreds. Many of our aviators to-day would be rich beyonds the dreams of avarice had they but one dollar for every mile they had flown.) Simultaneous with this feat we had a production (which was the co-operation of Glen Curtis, Dr. Graham Bell and J. A. D. McCurdy),



a machine known as the June Bug. In the same year they produced a Box-type machine which won the Gordon-Bennett race at Rheims. It was about this time that the Antinette monoplane appeared. It was a machine of this type that the late M. Latham made his first attempt to fly the English Channel. It was in these years that meets were held at Doncaster and Blackpool, England, and the author well remembers the gracefulness of the Antoinette as she conquered the air and many were the compliments heaped on this machine. This type became extinct about 1911. It was at this stage in the history of aviation that the first German to fly, Hans Grade, appeared in his early struggles on a Demoiselle type of machine, a machine after the style used by Santos Dumont, bamboo being used very largely in the construction of it. A notable machine around this period was the Brequet, carrying as many as eight passengers. It was on a later design of this type that the late Mr. Moorhouse (who has since won immortality and the V.C. in this war) flew the English Channel with Mrs. Moorhouse and Mr. Ledeboer as passengers.

Aviation and the World War

From this time on, aviation has slowly, but surely progressed and at the sound of battle, interest grew apace. What laughter there was when our little air fleet sailed away in the skies to France. People, uninitiated, scoffed and jeered at these frail and puny creatures going



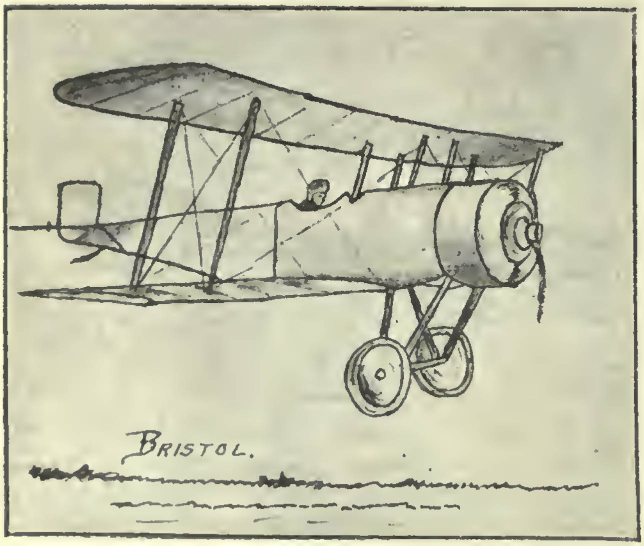
into the stern business of war. But with what success have these earlier achievements been endowed. As we have followed the history of the Great War, so we have been led to see the vast developments that have taken place in aviation. From frail-looking and undependable machines have grown mammoths of the air, giants of warfare, and the world has at last realized that aviation is an accomplished fact and not a fantasy of the brain. Oh! the wonders that have been performed and the help that has been given by the all-seeing eye of the observer as he scouted for the artillery or as he kept watch on the enemy's movements for our men in the trenches, and also the relief which the aeroplane has been able to bring to forces surounded by the enemy. It is not possible in such a short narrative to describe at all adequately the value and assistance which the aeroplane has rendered towards the attaining of the great victory. The multitudinous designs of machines which the war has brought forward are much too varied in type and too well known for me to make any attempt to describe their features. Fast scouts, fighters, heavy bombing machines, etc., are now handled with as great an ease as is the automobile. All this is the result of a few years' efforts, and now that victory is ours, why should not this great work go on?

The Power and Speeds

In discussing the evolution of the aeroplane it will perhaps be of interest to note the development which has taken place as regards the engines, the relative speeds of machines and the weights carried. The horse powers of engines have increased from 20 h.p. up to 800 h.p. and in one or two of our latest experimental planes as high as 1,000 h.p., the number of cylinders ranging from 2 to as many as 24 for one single engine. The Circuit of Britain was won on a machine fitted with a seven-cylinder engine of 50 h.p. In 1912, one of the naval machines, the Deferdussin, with a 70 h.p. Gnome, made a speed of 135 miles per hour. In June, 1913, a Pounier Pagney racing monoplane with a 160 h.p. Le Rhone engine competed in the Gordon Bennett race, doing approximately 130 miles per hour. We have machines now that can scale to a height of over 20,000 ft. in a remarkably short space of time, whereas, a few years ago, heights of less than half this distance remained unknown. Machines have risen as far as carrying passengers from the solo and dual machine to real passenger trains, carrying now as many as 30 and more people.

And What of the Future

It would be a stigma on the present generation were we to allow the progress of aviation to be hindered.

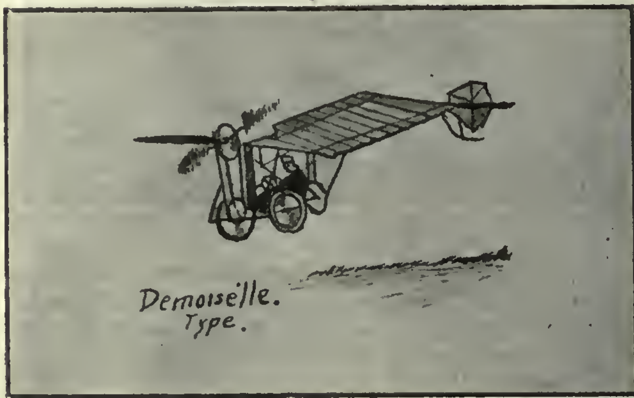


There are still yet fields to be conquered and objects to be attained, and now is the time for the rising generation to take up this new industry. Think of the field which is open to it here in this country. A country with thousands of miles unopened, uncultivated and uninhabited, because of the difficulties of transportation. Long, tedious train and seas voyages will fade into oblivion and short, pleasant aeroplane trips will put us in closer communication with our lands, our people and our friends in other countries. Then again, with the advance in aviation, would come its attendant success of commercial life. Factories, schools, aerodromes, repair shops and all the other accessories to flying would spring into being, bringing with them labor for thousands from the scientist down to the humblest laborer. Surely after all that has happened these past few years, aviation will not be allowed to remain stagnant. No, let not these pioneers (some of them dead) turn again and say that as a nation we lack enterprise, but let us carry forward the work so that nations may profit and humanity at large can derive those benefits which our pioneers intended we should reap.

WHAT CANADA HAS ACCOMPLISHED

IN the report issued by the Imperial War Cabinet for the year 1917, Canada's services to the Empire in the production of munitions was referred to as follows:

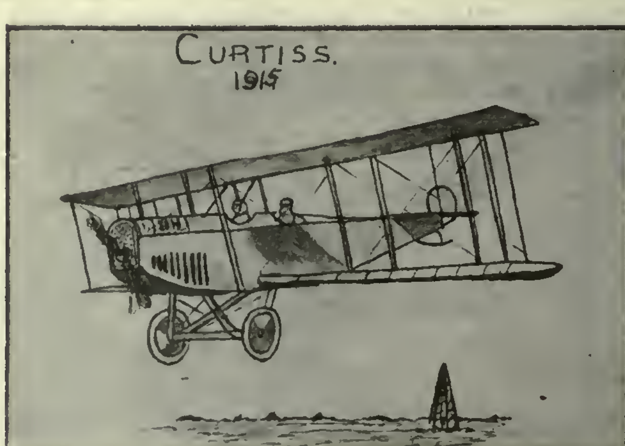
"Canada's contribution during the last year had been very striking. 15 per cent. of the total expenditure of



the Ministry of Munitions in the last six months of the year was incurred in that country. She has manufactured nearly every type of shell from the 18-pdr. to the 9.2". In the case of the 18-pdr., no less than 55 per cent. of the output of shrapnel shells in the last six months came from Canada, and most of these were complete rounds of ammunition which went direct to France. Canada also contributed 42 per cent. of the total 4.5 shells, 27 per cent. of the 6" shells, 20 per cent. of the 60-pdr. H.E. shells, 15 per cent. of the 8" and 16 per cent. of the 9.2". In addition, Canada has supplied shell forgings, ammunition components, propellants, acetone, T.N.T., aluminium, nickel, nickel matte, aeroplane parts, agricultural machinery and timber, besides quantities of railway materials, including no less than 450 miles of rails torn up from Canadian railways which were shipped direct to France."

The Right Kind of Steel

Experiments were conducted shortly after the outbreak of the war with steel made in Canada, with a view of securing something more nearly approaching an adequate supply of shrapnel. It is revealing no State secret to say that in those early days of the war the supply of this form of explosive on the Western front was



perilously inadequate. Basic steel, the only kind made extensively in Canada, was suitable, and it was in the month of December, 1914, four months after the outbreak of the war, that Canada made her first shipment. By the end of May, 1915, approximately four hundred establishments in Canada were engaged in production.

Recent Promotions in Grand Trunk Shops

R. J. Needham, Chief Engineer, G.T.R.

R. J. NEEDHAM, recently appointed to the position of chief mechanical and electrical engineer of the Grand Trunk, with headquarters at Montreal, was born on January 11, 1882, at London, Ontario, in which place he acquired his early education. After graduating from the London High School, he managed a plumbing and heating business for four years. In 1906 he entered McGill University as an undergraduate in applied science, specializing in electrical engineering, and graduated with the degree of B.Sc. in 1910. He was employed in the erection and testing department of the Connecticut Dynamo and Motor Works of New York, from May to October, 1907. In May of the following year he accepted a position as inspector of electric locomotives and operation for the Grand Trunk at St. Clair Tunnel. During the summer of 1909 he was employed by the New York Edison Co. in their testing laboratory at the Waterside Station No. 1 in New York City. During 1910-11 he was engaged by the Detroit Edison Co., first in construction work and afterwards as chief operator. From 1911-18 he held the position of electrical engineer with the Grand Trunk Railway, and in September, 1918, he was appointed to the dual position of chief mechanical and electrical engineer with the same company.

R. J. NEEDHAM

W. A. Booth, Chief Draughtsman G.T.R.

WILLIAM ALFRED BOOTH was promoted to the position of chief draughtsman of the Grand Trunk motive department on October 1, 1918, after serving in the capacity of assistant chief for the past ten years. Mr. Booth was born in Montreal and received his early training in the city schools under Prof. S. H. Parsons. Twenty-five years ago he started as junior draughtsman with the Grand Trunk at Montreal. During his early years with this company he attended classes under the jurisdiction of the Mechanics' Institute, and freehand classes under the Council of Arts and Manufacture of the Province of Quebec. For many years he was elevation draughtsman for the Grand Trunk. Mr. Booth is much interested in the welfare of the younger element and for some time has been instructor of apprentices on the subjects of geometry and mechanical drawing.

W. A. BOOTH

W. J. Hyman, Car Dept., G.T.R. Motive Power

W. J. HYMAN, who was recently appointed chief draughtsman of the car department of the Grand Trunk, with headquarters at Montreal, was born on Aug. 9th, 1882, at Radstock, Somersetshire, England. Following his public school education he served a six-year apprenticeship at car design and construction. In 1903 Mr. Hyman came to Canada and worked in the car department of the Grand Trunk until 1905, when he was transferred to the car department drawing office, acting in the capacity of draughtsman until 1913, when he was appointed to the position of assistant chief draughtsman. Mr. Hyman has always taken a great interest in the younger boy and was instrumental in organizing the car department apprentices' classes in 1911, with courses in mathematics and mechanical drawing, supervising these classes up to May, 1918, when the motive power and car department classes were merged into one. He was promoted to his present position on the 1st October of this year.

W. J. HYMAN

W. H. Hicks, Winnipeg

W. H. Hicks, 567 Banning Street, Winnipeg, has taken over the Canadian Sirocco line for Manitoba and Saskatchewan, also Western Ontario, including Port Arthur and Fort William. He will handle their regular lines of ventilating fans, steam traps, and high-speed vertical engines.

W. H HICKS, WINNIPEG

Quebec's annual production of pulp-wood exceeds 1,000,000 cords. Ontario comes next with about 800,000 cords.

It takes, approximately, 1½ cords of wood to make a ton of paper.

Spruce trees, best suited to the production of pulp, require from 100 to 150 years to arrive at maturity.

Forest fires are a source of great loss to the Canadian pulp and paper industry and eat up millions of cords of wood-pulp every years.

Where coal is used to generate power in the operation of paper mills it takes, approximately, a pound of coal to produce a pound of paper.

The average labor cost of producing a ton of paper has increased 75 per cent. in the period of 1912-1918.

More Efficient Methods Follow War Work

What Has Shell Making Meant to the Canadian Trade?—The Creation of the Special Machine—Standardization Means Much to the Factories and May Figure in Future Operations

By J. H. RODGERS, Associate Editor Canadian Machinery.

WITH the cessation of shell making, Canada brings to a close one of the most rapidly developed and most extensive industries ever engaged in by manufacturers in this country. The many plants involved in the production of the various types of munitions are not yet cold from the unprecedented activities of the past four years and it may be a little early to dwell on the possible development contingent on the experience acquired by those associated in this enterprise, but it is not beyond the pale of reasonable thought to anticipate remarkable changes in the post-war methods of manufacture, as a result of the practical knowledge thus attained. While we all recognize the regretable features of a war of the magnitude of the one just recently brought to a close, we cannot but realize that many lessons have been taught us from which we as a nation, and likewise the world at large, should ponder over and assimilate into our further efforts so as to assure a profitable period of continual prosperity in moral, social, commercial and industrial activity. It is more concerning the latter of these four with which the present article has to deal.

One of the outstanding features that has characterized the notable achievements of shell production was the high point of efficiency that had been attained during the past year of the work. When one looks back and recalls the early struggles in connection with the making of shells and the obstacles that had to be overcome during the incipient stages of the industry, it reflects great credit on those responsible for the progress that has been made in this important phase of war development. Before touching on the many changes that are likely to influence future manufacturing methods, it might be well to review some of the causes that were primarily responsible for this wonderful evolution. It must be remembered that very little was known about the manufacture of munitions in this country prior to the opening of hostilities in 1914; what small quantities had previously been produced being made in the arsenal at Quebec, and for this reason the Canadian manufacturers were dubious about undertaking a task about which they knew virtually nothing. However, despite the fact that little reliable information could be obtained respecting the existing methods of shell production, the urgency of the need was so imperative that little hesitation was shown once it was decided to undertake the work. One of the factors that prevented early efficiency in the production of shells was the general impression that the war would be a short one. With this in mind and the lack of knowledge then available regarding production on a basis it has since attained, the early practice of shell-making was naturally along the lines with which the engineers in this country were more or less familiar. With the thought of a short war before them, those firms that were acquiring machinery for the purpose of shell-making, did so with the intention of utilizing this equipment for subsequent operations in connection with their regular business. Under these conditions it will readily be seen that the bulk of the initial shell machinery was of the standard pattern, and minus the experience of systematic production, the tools ordered for future operations were also of standard design and construction, single purpose machines being a later development.

Early Difficulties

ANOTHER feature that had considerable bearing on the machines adopted was the belief that high-grade machine tools were the only kind suitable for the purpose, and that accurate adherence to specifications and dimensions was only possible with the best equipment. Had the war been of short duration it is safe to say that the evolution of shell-making would not have gone very far beyond the practice of 1914; but those pre-war methods of shell production are, and will likely remain, a matter of history. It was early in 1915—and after renewal orders had been placed for shrapnel—before the manufacturers here began to realize fully the magnitude of the task and the urgent necessity of accelerating production, not only on the shrapnel but on the heavier high explosive shells that were then required. The utter inability to obtain standard equipment at this time was, as then thought, the chief drawback to speedy production, and while this feature was a source of general annoyance at the time, it undoubtedly proved a boon in disguise. This factor of the early troubles of the Canadian manufacturer, together with the apparent impossibility to obtain definite data or information respecting the recognized methods of shell production, were the two outstanding causes that led to the development and adoption of the special equipment now used for this specific purpose

Creation of the Special Machine

THE industry had rapidly spread from coast to coast and within a very short time the majority of the metal working plants in the country were engaged, or contemplated engaging in the making of shells or some of the component parts. As said before, tools of a suitable character were very hard to obtain and many firms securing contracts often found that eight or ten months must elapse before they could secure machinery. This long delay was almost prohibitive and in order to meet the immediate demand for shells it became imperative to devise means whereby operations could be carried on, even though it be on greatly reduced scale. Little could be gained from the experience of others and, therefore, each individual plant organization had to rely on its own initiative and resources for the development of tools and attachments to supplement the existing equipment, or that otherwise available. The so-called scrap heap became a very valuable asset overnight, and many a machine was reclaimed and placed back into service for profitable work in connection with certain operations. The adoption of special attachments on many of these machines was the basis of a great number of the single purpose tools subsequently designed for many of the detail operations relative to the machining of the shells. From these impromptu devices have been evolved nearly all the special machines now recognized as the most efficient for the manufacture of munitions. It is perfectly safe to state that if the industry were to be renewed at a future date—and we trust this may never be—that machines acknowledged as standard tools would receive no consideration in regard to the actual work on the machining of the shell. A trip through the average shell plant a few months back would demonstrate to what extent the "standard" tool has been eliminated from this particular industry. Nine-tenths of the equipment—exclusive of that used in the tool making departments—is of a type suitable only for the operation for which it was originally designed.

The question has often been asked as to the future of these machines. The answer regarding the bulk of the "shell machinery" is—nothing but food for the cupola. This, however, does not apply to the single purpose machine in general, as experience has exemplified the great efficiency of this class of equipment for repetition and standardized production, where the same is carried on on an extensive scale.

One of the lessons that has been learned from this great industry is the possibilities of greater co-operation for a more systematic basis of manufacturing articles in large quantities. What has been achieved in time of war could well be accomplished in times of peace, providing the same spirit of co-ordination permeated the producers of material.

Routing of Work Essential

ONE of the essential factors of efficiency is the elimination of waste effort, and production engineers are ever striving to minimize this objectionable feature. One of the fundamental requirements of economic standardized production is the routing of the work during the process of manufacture. This question was given very little consideration during the incipient stages of munitions making, with the result that the handling of the shells from one machine to another was frequently more costly than the actual machining operations. Where machine shops already established took up the work of shell making it was often a difficult problem to utilize the available equipment to the best advantage, without re-arranging the entire layout, and not infrequently additional tools were located in a haphazard manner throughout the shop, with little thought to the sequence of operations, so that it was necessary to transfer the work back and forth during the process of manufacture. In shops where such conditions existed it was next to impossible to secure from the equipment the output which would have resulted from a better arrangement of the machine tools.

Where additions to existing factories were required, or where new plants were built, the routing of the work was given the first consideration, so that the machine installation was of such a character as to eliminate any unnecessary "backing up" of the work in its progress through the shop. What has been true in respect to shell making is equally true in almost any line of manufacture, and it is an essential fundamental that successful work of a repetition character cannot be carried on unless careful attention is given to this important problem of work routing, a factor that, in the past, has been very often sadly neglected.

The Shell Mechanic

ONE phase of recent activities that must not be overlooked as having a bearing on future enterprise, is the great number of men and women that have acquired, from their sojourn in the shell plants a certain percentage of mechanical skill and knowledge resulting from their continual operation of the different machines. It may be said that few of these men would be fitted to fill the position of a mechanic in ordinary industrial practice, but we must acknowledge that this is the day of specialists, and post-war manufacture will be developed along these lines more than ever they were in the past, and the experience they have gained during the past four years may well fit many of them for a position as a machine operator where considerable quantity of work is performed on a repetition basis. Then again, many of these men, who before the war were in positions where the remuneration was comparatively low in relation to their "war wages," may feel inclined to remain at a class of work assuring greater compensation. On the other hand, shell work on the whole has been a killing job, and many of those recently engaged in the industry may be only too pleased to return to their former occupations. It is quite certain, however, that very few will have acquired sufficient elementary mechanical knowledge or experience to assure for themselves a place in a plant where general all-round ability is essential, so that it is very unlikely that the engineering field will be seriously affected by the available supply of "shell mechanics." This, however, may be one of the problems of the reconstruction period.

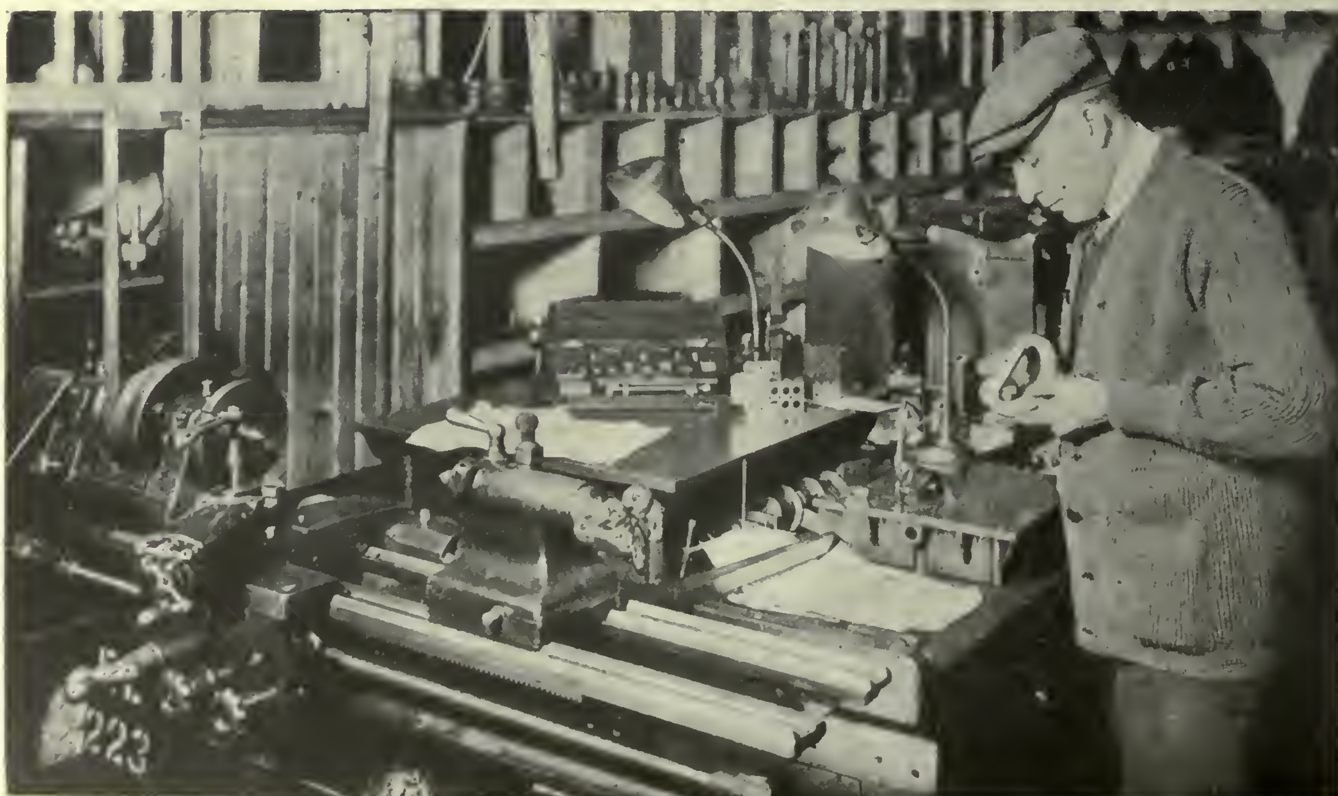
Progressive Inspection Very Important

ONE essential to the successful achievement of manufacturing where the work involves a number of different operations on one or more pieces. is that of progressive inspection. It was clearly demonstrated during the first year of the war that the only assurance of effective production was by a thorough inspection of the work at stated intervals during its semi-finished state. The importance of keeping within the specified limits of tolerance, both as regarded dimensions and weight, was not duly recognized by many of those pioneers engaged in the work, the consequences being that in many instances large quantities of finished and semi-finished shells were rejected by the Government inspectors. It was frequently the case for firms to have elaborate inspection of their own just prior to the work going to the Government cage, little previous attention being given to the checking of the work in its earlier stages. This invariably resulted in a large percentage of the work being returned for some slight alteration or correction. It was soon seen, therefore, that to minimize the factor of shell rejections it would be necessary to have a closer examination of the product after each operation, so that faulty work of the machine or the operator could be corrected immediately, thus avoiding the accumulation of spoiled work or the exaggeration of the defect on the following or subsequent operations. This method of inspection might be considered too costly for work other than munitions, but when the advantages are weighed against the disadvantages it will be found that the economic factor is in favor of its adoption.

Standardization Stimulated

IF one were to ask the question—what was the predominating feature of shell production? the answer would invariably be—standardization. In the past many firms have prided themselves on the standard character of their product, and in many respects have been able to substantiate the statement, but the mechanical industry as a unit has had little conception of what the term "standardization" actually meant. Here again the activities incidental to the prosecution of the war have taught us many lessons. No greater advancement has been made toward the zenith of standardized practice than the methods adopted for checking the dimensions on the shells and component parts. In ordinary industrial establishments the practice was localized almost entirely to the plant in which the product was made and afterwards assembled, so that little expense was entailed if some corrections were required. The great national industry recently engaged in, amply demonstrated the imperative necessity of working within certain specified limits of measurements, to assure undisputed accuracy of all dimensions, so that no difficulty would be encountered when assembling the various parts, irrespective of where these different pieces had been produced. A machined dimension at the Pacific must correspond with a similar dimension at the Atlantic coast, within the limit of tolerance, be this ⅛ of an inch or 1-10,000 of an inch, otherwise standardization or interchangeability becomes a negative quantity.

With the possible exception of a few tool or automobile manufacturers it is doubtful if more than 20 per cent. of Canadian metal industries had been accustomed to



WAR HAS DEVELOPED THE ART OF GAUGE MAKING TO A HIGH STATE OF PERFECTION.

working to the fine limits or low tolerances required in shell specifications. Yet to-day there are tens of thousands of men and women, who, before the war, did not know the difference between 1-32 and 1-1,000 of an inch, and are now capable of measuring limits of a few thousandths as easily as a carpenter measures a twelve-foot board with his two-foot folding rule. The reason is—the limit system. These same men and women may still be ignorant as to what an actual dimension is, but the fact remains that they have accomplished remarkable results due, not to their knowledge of fine measurements, but rather to their ability to use the gauges that are provided for the purpose.

Passing of the Spring Caliper

IT would be virtually impossible for a staff of experienced mechanics, working with the old style spring or friction joint calipers, or even with the standard micrometer, to maintain the speed and accuracy acquired by these "shell mechanics" with their limit gauges. Naturally the gauges required careful checking at intervals, but once set to the desired limits of "go" and "no go," the operator's only concern was to see that the limits were adhered to; it did not matter to him, or did he even know, probably, whether the size was an inch or a foot.

Standardization is a big problem, but the war has given a stimulus to its further adoption that will eventually eliminate the pre-war indifference so prevalent among many manufacturers. There is no reasonable argument why an inch should not be an inch, yet how many mechanics would produce the same size hole or plug if given the work to do? The feel or touch of no two men is exactly alike, therefore, the size would vary accordingly. With the limit system this would be avoided.

Importance of Proper Gauges

IT must not be supposed that the advantages of a limit system are confined to work where the tolerance is only a few thousandths or fraction thereof; the system may be applied economically to work where the tolerance is as high as 1-32 or 1-16 or even greater, the nature of the work and its intended purpose being the determining factors. Nor should the volume of the product prevent the adoption of a fixed standard, for with modification the practice is as economical in one line of manufacture as another. Some time ago the superintendent of a certain plant had six small intricate pieces to make, which, under ordinary conditions would have been performed in the usual manner of making each piece separate without gauges or jigs, using only the general tool-box outfit. The initial expense of making a jig and gauges necessary for the work consumed nearly all the profit that might have been made without them, but it was the policy of the shop to have fixtures and gauges made for everything where there was the least possibility of renewal orders. In this particular instance the initial six articles were supplemented by twelve others, so that with the facilities previously provided, the last twelve were turned out in one-quarter the time taken on the first six, and the entire eighteen were practically identical. As an economic feature alone, the question of standardization should receive the immediate attention of every manufacturer, for its early adoption means national as well as individual efficiency, two factors that are of imperative necessity in the present period of reconstruction and world competition.

Future Opportunities

FEW will deny that, before the war, the world at large was dependent—unconsciously perhaps—on Germany for certain classes of brains and materials. The experience so forcibly pressed home to us during the war period should not, however, permit of us again placing ourselves at the industrial, commercial or intellectual mercy of such a country as Germany, or in fact any other. Some may contend that this policy will be closely adhered to by the people of the Allied countries who have suffered so much from the depredations of the Huns, but with the patriotism gradually dying out, the commercial world will soon return to the monetary basis, so that the exclusion of German products must be solved by our own manufacturers in producing economically every type of goods that will clash with those of other countries.

The progress that has been made must not stop with the stoppage of the shell industry, rather should the experience be a stepping stone to still greater achievement. The revolutionary changes that have taken place in nearly all lines of manufacture will make it almost impossible to revert back to the old course of pre-war days. Industrial development, scientific and practical, has been of such a character that post-war activities will be conducted with a wider and more expert knowledge than ever before. The rapid advances that have been made in the manufacture of steel and the extensive experiments that have been carried out, will place this industry in a much superior position, and will form a basis for still further developments in this and allied industries.

Future of Machine Tools

THE vast amount of machine tools that have been utilized for the shell industry has frequently been used as an argument in favor of a period of depression in the machine tool activity. There is considerable divergence of opinion on this matter, and therefore, a prediction in either direction might be sadly amiss. Much will depend on the length of the period of post-war adjustment that must inevitably follow on the heels of a great war. It is quite reasonable to anticipate a brief spell of inactivity before reconstruction gets into full swing, but there is little to indicate that an indefinite space of time must elapse while these shell shops are unloading their equipment on a waiting market. These tools have been in constant use from 15 to 24 hours a day for from two to four years, and in the charge of men whose only thought was the machining of the shell, the care of the tool itself not coming within their line of vision. The specific design of the majority of these machines is the chief argument against their adaptability to ordinary commercial use. Where standard tools have been utilized for the purpose the nature of the work will naturally have deteriorated their value for general machine shop practice. It would therefore seem that shell machinery—apart from that used in the tool rooms, which has been operated by experienced mechanics—will not be a reactionary factor on machine tool activity. These special machines will, on the other hand, open the way for changes in the design of standard equipment that may eventually mean a period of increased prosperity for machine tool builders.

Experience in shell making has shown the possibility of improved methods in cutting and removing metal, which, under pre-war conditions, could not be met with the existing standard tools. Manufacturers, having seen the efficiency of changing machine design and construction will want the very best for the development of their future activities. This not only applies to Canadian industries but likewise to every country involved in the war, and to many of the so-called neutrals. The peoples of the world have been thrown into closer contact than ever before and greater all-round efficiency will be the natural consequence. Manufacturing will be the basis of this efficiency and therefore economic production will be the keystone of every country's development, so that everything detrimental to progressive activity will eventually be replaced by up-to-date methods and practice.

Canada's Part in Beating the Submarine Peril

Many Trades Are Called in When a Ship Contract is Secured For This Country.

Can Canada Go Ahead and Compete With British Owners When Cost is Taken Into Consideration?

By T. H. FENNER, Editor Marine Engineering

NOW that the tension is ended, and we have time to look back, Canada's effort in damming the drain on the Allies' shipping stands out as strong as that of any.

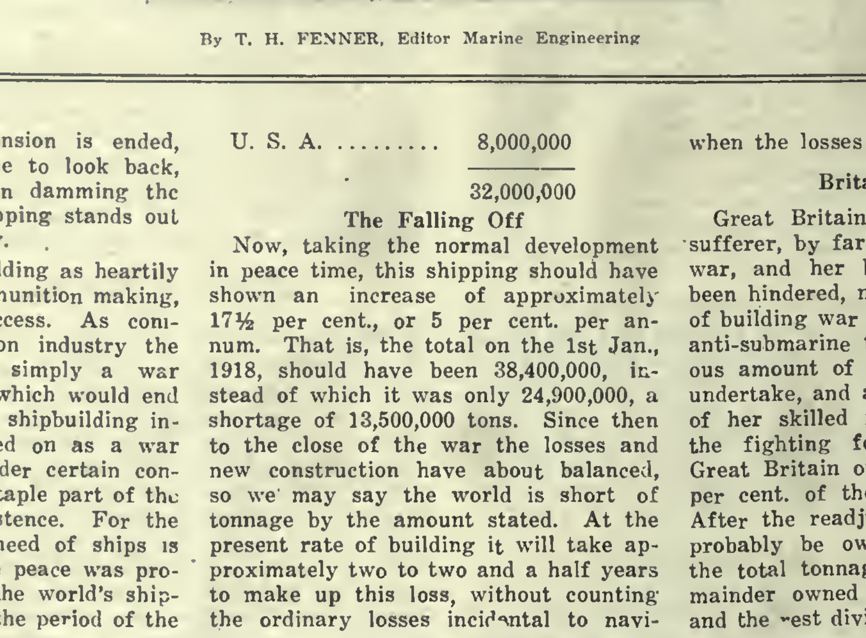
She went into shipbuilding as heartily as she entered into the munition making, and with as much success. As compared with the munition industry the latter was purely and simply a war measure, the utility of which would end with peace, whereas the shipbuilding industry, primarily entered on as a war measure, is capable, under certain conditions, of becoming a staple part of the country's industrial existence. For the immediate future, the need of ships is just as urgent as before peace was proclaimed. The state of the world's shipping before and during the period of the war were about as follows: On Aug. 4, 1914, the total tonnage of allied and neutral countries was approximately 42,000,000 tons. Up to January 1, 1918, the total losses by mine and submarine were 9,500,000 tons, and by other marine casualties, 1,275,000 tons. This gives a total loss of 10,775,000 tons. Deducting this from the total at Aug. 4, 1914, we have 31,225,000 tons of pre-war shipping afloat. To this must be added the ships constructed during the same period, which amount to 4,485,000 tons, making the total at Jan. 1, 1918, 35,710,000 tons. This is a decrease of 6,290,000 tons. Taking the Allied Nations alone, the position on Aug. 4, 1914, was about as follows:

Great Britain	20,000,000 tons
France	2,300,000
Italy	1,700,000
U. S. A.	8,000,000
	32,000,000

The Falling Off

Now, taking the normal development in peace time, this shipping should have shown an increase of approximately 17½ per cent., or 5 per cent. per annum. That is, the total on the 1st Jan., 1918, should have been 38,400,000, instead of which it was only 24,900,000, a shortage of 13,500,000 tons. Since then to the close of the war the losses and new construction have about balanced, so we may say the world is short of tonnage by the amount stated. At the present rate of building it will take approximately two to two and a half years to make up this loss, without counting the ordinary losses incidental to navigation in peace times, from marine casualties, and ships going out of commission through ordinary depreciation, or old age.

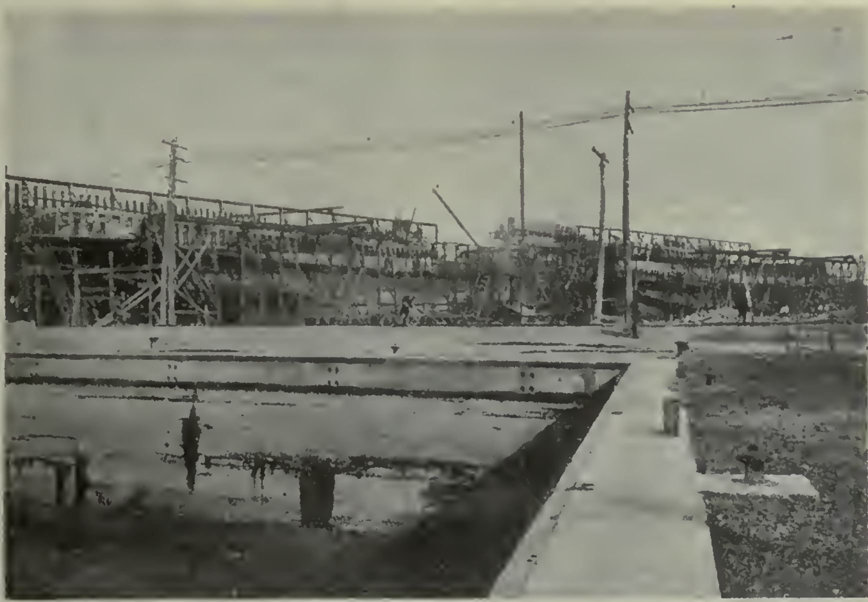
The distribution of the world's tonnage will show a considerable difference when the losses are finally made up.



ONE OF THE OLD BRIGADE

Britain Hard Hit

Great Britain has been the heaviest sufferer, by far, from the losses due to war, and her building activities have been hindered, not only by the necessity of building war vessels, especially of the anti-submarine type, but by the enormous amount of repair work she had to undertake, and also the fact of so many of her skilled men being drafted into the fighting forces. Before the war Great Britain owned and operated fifty per cent. of the total world's tonnage. After the readjustment period she will probably be owning only one-third of the total tonnage, with half of the remainder owned by the United States, and the rest divided between the remaining maritime nations. Competent authorities estimate the total deadweight tonnage in 1914 at 60,000,000 tons. If this total is again realized two years after the close of hostilities, it will mean that Great Britain will own 20,000,000 tons, the United States the same, and Japan, France, Germany, Norway, and the smaller maritime nations divide the rest between them. In the British total the tonnage of the Dominions of the British Empire has been included. This was because the shipping of the Dominions combined were but a small percentage of the total British shipping, and most of their ships were built in Great Britain and remained under English registry. Australia and New Zealand got practically all their ships built in Great Britain, and in Canada the building was confined mostly to smal:



WOODEN SHIPS ON THE WAYS

vessels, many of them wood. On the Great Lakes there were some good sized steel vessels built for Canadian registry by Canadian builders, but most of the lake freighters were built in U.S. yards.

The Effect of the War

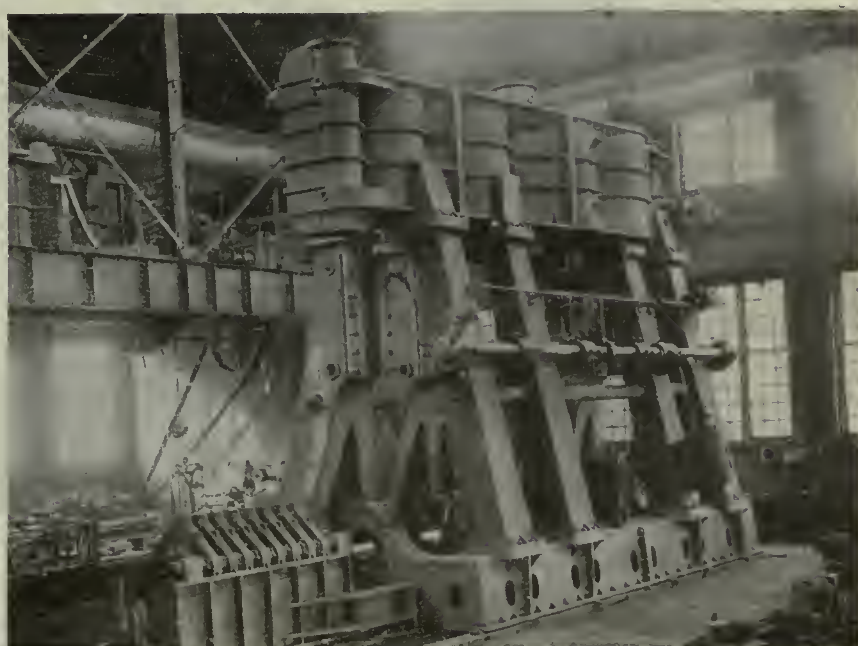
Before the war, Canada's mercantile marine was confined to the lake steamers and small coasting vessels. The United States was in the same position excepting that they had a large fleet of coasting steamers, due to the fact that under the United States laws no vessel can trade on their coasts unless they are under the American flag. A large part of Canada's coasting trade was handled by Norwegians. The United States, since coming into the war, has entered into a shipbuilding programme that will raise her, in two years more, from a negligible factor in the marine world, to a position of equality with Great Britain, the proud mistress of the seas. Canada, in order to contribute to the urgent war need for ships, jumped into the shipbuilding game with a vim, and achieved wonders, and now that peace has come, intends to carry on the good work, and have her own merchant fleet to carry her own goods. The Canadian Government has entered into quite extensive operations in the ship-owning line, and will, in the near future, be the owners of 39 large steel cargo vessels. These will represent a large investment, and the country will have keen interest in watching their future operations, whether they are financially successful or otherwise.

Canada's Achievements

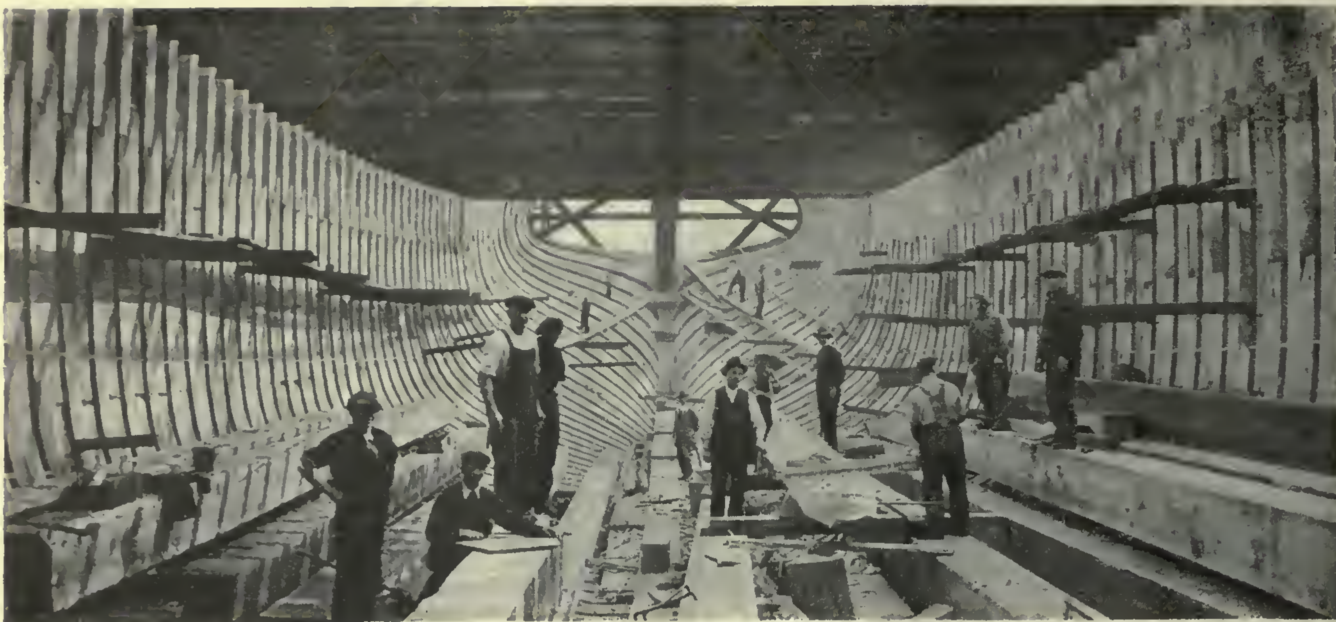
At the beginning of the war, Canada's shipbuilding activities were limited to some construction on the Great Lakes, small wooden vessels round the coasts of the Maritime Provinces, and wooden vessels of varying sizes up to 1,000 tons on the B. C. coast. On the St. Lawrence the Canadian Vickers had established a modern shipbuilding and ship-repairing shop, with a large floating dry dock at Montreal, and further down the river there were other dry docks and yards. The Canadian Government had a ship yard and repair shop at Sorel, and at Quebec were the yards of the Davie Shipbuilding and Engineering Co. The Canadian Vickers yard at Montreal is the Canadian branch of the English firm of Vickers Maxim. The Naval dockyard at Halifax was practically shut down, and the same might be said of the one at Esquimault. This was the result of Sir John Fisher's policy when First Lord of the Admiralty. At the end of 1914 there were on the books of the Canadian Registry 8,772 vessels. Of these, 4,054 were steamers, of a gross tonnage of 744,783 tons. This gives an average of less than 200 gross tons each, in fact there were only one hundred and ninety-two steamers of over 1,000 gross tons on the register. At the end of 1917 there were 221 steamers of over 1,000 tons registered in Canada, but a good number of vessels had been built for export.

The Contracts Came

The Imperial Munitions Board, which was created in 1915, turned its attention to shipbuilding, with the result that contracts were given in Canada for 43 steel ships, and 58 wooden ships, with a total deadweight capacity of 360,000 tons. The value of these contracts was $70,000,000, and was divided between British Columbia, Ontario, Quebec, and a small portion to the Maritime Provinces. There are at present in Canada 45 berths for building steel vessels of 3,000 tons up to 10,000 tons, besides the yards devoted to wooden shipbuilding. The ships for the Imperial Munitions Board to be launched this year, both steel and wood, are 79 in number, aggregating 318,400 tons deadweight. Besides these ships, 11 steel vessels have been built for the Marine Dept. of the Government, with a capacity of 48,000 tons. For private owners, 14 steel vessels with a deadweight of 62,400 tons have been built, as well as 8 wooden vessels of 17,800 total deadweight. These figures are all for vessels of over 1,000 tons. Besides these vessels, Canada has supplied 550 submarine chasers for the Imperial Government, and 36 for the French Government. A number of drifters and trawlers have also been supplied to the Imperial Government. Truly, this is a remarkable effort, considering the amount of work that the country was putting into its munition industry, and taking into account the handicaps which the industry was up against. Labor of the right kind was hard to get, and in too many cases, hard to get along with.



TRIPLE EXPANSION ENGINES OF SS. HAMONIC. BUILT BY COLLINGWOOD SHIPBUILDING CO.

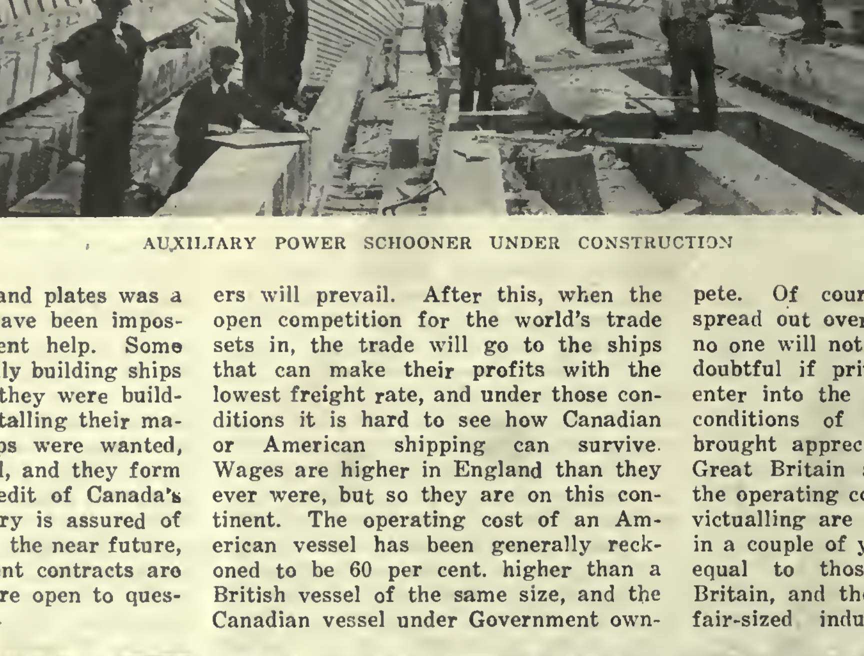


AUXILIARY POWER SCHOONER UNDER CONSTRUCTION

Securing steel sections and plates was a hard task, and would have been impossible but for Government help. Some of the yards were actually building ships at the same time that they were building their shops, and installing their machinery. However, ships were wanted, and they were furnished, and they form another item to the credit of Canada's war effort. The industry is assured of a period of prosperity in the near future, but after the Government contracts are through, its prospects are open to question.

Looking to the Future

Figures are obstinate things, and there is no burking the fact that to build a ship in Canada at the present time costs $200 per ton, against $120 per ton in England. Repairs cost about 80 per cent. higher on this side of the Atlantic, and several cases can be quoted where vessels have been towed several thousand miles to an English repairing yard, rather than have extensive repairs made abroad. The Canadian Government has expressed its intention, which is being carried out, of building a mercantile marine. This will be operated as a stock company by the Railway Board, and its profits or loss will be easily seen. Till the merchant fleet of the world gets back to its normal standing, an era of high freights and profits for ship owners will prevail. After this, when the open competition for the world's trade sets in, the trade will go to the ships that can make their profits with the lowest freight rate, and under those conditions it is hard to see how Canadian or American shipping can survive. Wages are higher in England than they ever were, but so they are on this continent. The operating cost of an American vessel has been generally reckoned to be 60 per cent. higher than a British vessel of the same size, and the Canadian vessel under Government ownership will approximate near to that. A capital investment of $200 per ton against $120 per ton means 40 per cent. higher, and if operating costs are only 30 per cent. higher, it is hard to see where the Canadian vessel could compete. Of course, the losses will be spread out over the whole country, and no one will notice it much, but it seems doubtful if private firms will wish to enter into the shipowning business. If conditions of building cost could be brought appreciably near to those of Great Britain and European countries, the operating costs, so far as wages and victualling are concerned, will probably, in a couple of years from now, be fairly equal to those prevailing in Great Britain, and there will be a field for a fair-sized industry in Canada. The establishment of plate mills in Nova Scotia, Ontario, and perhaps later in B. C., would help materially in reducing costs of building, while the adoption of standard ships would reduce the amount of skilled labor required, this also tending to make first cost less. In the meantime, the Government contracts and those for export will keep the yards busy.



LAUNCHING A 3,500-TON STEEL SHIP

The Wooden Ships

There are 313,000 tons of wooden shipping building for export, while the Government's contracts for its 39 ships amount to 250,500 tons and a cost of about $45,000,000.

The building of a ship entails the employment of practically every trade known to man, and calls in dozens of other industries to supply equipment. We find the work of instrument makers, represented by the compass, telescopes, binoculars, etc. The hydrographic experts are represented by the charts, and the publishing business by the various books of sailing directions, tide tables, navigation tables, etc. Here also is the ship's telegraph, usually made by some firm specializing in these instruments, which afford the means of communicating orders from bridge to engine room, forecastle head, and poop. The wireless apparatus, steam boilers, engines, ship's lamps, binnacle lights, etc., pulley blocks, snatch blocks, gin blocks, anchors and chains, winches and windlass, steam and hand pumps, are all parts of equipment calling in the services of specialists. The carpenter lays the decks, and the joiner does the fitting up of cabins. The upholsterer is needed here, too. Electricians to do the wiring, plumbers for the sanitary arrangements, painters, nickel platers, French polishers, marine engineers,—the list is endless. Such an industry is worth holding if at all possible, but that means it must be self-supporting. An industry which is kept going by the help of one part of the population to keep another part in employment, is not a good investment for the country. It reminds one of New Zealand, of which it has been said that one half of the country pays taxes to pay the other half for collecting them

Various Types of Ships Built

The scarcity of steel, and its high price, together with the difficulty of getting skilled men, turned the attention of shipbuilders in the Allied countries to the use of other materials, and to quicker methods of handling the construction of steel vessels. The fabricated method, adopted in Great Britain and the States, of building steel ships, has materially shortened the period of building. In this method a standard size and type of ship is determined on, the scantlings of which can be made at any steel construction shop, and then shipped to the various yards where the hulls are being built. This eliminates an enormous amount of work in the moulding loft. Some work has been done utilizing electric welding instead of riveting, but this is largely in an experimental stage. The building of large vessels in concrete was the most radical departure made. The wooden vessel was but a reversion to an old type, and was confessedly a substitute, and not a rival to steel, and while concrete barges and boats of small sizes had been built at various times since about 1850, the construction of large vessels of ferro-concrete was something absolutely new. Its future is doubtful, for reasons which will be discussed later on in this article. The steel and wooden vessels fitted with internal combustion engines have increased considerably. Some of these depend entirely on the oil engine for propulsion, while others have the aid of sails. In Great Britain the steel cargo carrier fitted with heavy oil engines has attained a size of 10,000 tons d.w., and the appearances are that there will be a large expansion of this type when builders get time to turn more to peace construction. The turbine, driving through reducing gears, has been fitted in some large vessels, and the steam turbine driving the shafting through direct connected electric generators and motors, has had some highly successful applications.

3,500-TON STEEL SHIP AFTER LAUNCHING

Using Wind and Power

The auxiliary sailing vessel, by which is meant a vessel depending in the main on her sails for propulsion, but with power available when winds are light or unfavorable, is a good proposition in some particular trades owing to their lower running expenses and larger amount of available cargo space compared with a steamer of the same size. A large number of these vessels have been built on the British Columbia and American Pacific coast. For large high-speed vessels, such as first-class passenger liners, the steam turbine driving through a suitable reduction gear would seem to be the motive power of the future, while it is probable that for the ordinary cargo vessel up to 10,000 tons, the internal combustion motor will gradually replace the reciprocating engine. The triple expansion engine will die hard, but it would seem that with increasing experience the oil engine will be brought to as great a state of perfection in design and manufacture as the multi-stage steam engine, and then its inherent advantages as a heat engine will give it first place.

Reinforced Concrete vs. Steel

The steadily mounting cost of steel,

CAR FERRY "ONTARIO," NO. 2. BUILT BY POLSON IRON WORKS, TORONTO.

coupled with the necessity of producing ships quickly, with a minimum amount of skilled labor, led naval architects in Great Britain and the United States to the consideration of reinforced concrete vessels. As stated before, this was not a new method, the only thing being that it had not been used for vessels of large size. The first reinforced concrete boat was a small rowboat, built by a Frenchman named Lambot, of Carces, France, and patented by him in 1849. The next vessel of which there seems to be any record, was a sloop called the Zeemeuw, built in Holland in 1887, and reported to have been in constant service ever since. The firm of C. Gabelllini, Rome, between 1896 to date, constructed various lighters in ferro-concrete, and these have been satisfactory to the Italian officials. Concrete scows and barges have been constructed in various parts of the States up to 500 tons, a scow of that size being built in 1912 by the First Concrete Scow Construction Co. of Baltimore. In England and Norway concrete barges, dredges, etc., have been built at various times, and in Norway the practice of building barges bottom up and launching them that way was developed. The reason for this is that it lends itself to a better mixing of the material, and allows the use of a thinner covering of concrete over the steel. The largest vessel constructed of ferro-concrete has been the Faith, a 5,000 ton deadweight steamer built in San Francisco this year. Many extravagant claims were made as to the future of the concrete vessel, but it would seem that once normal conditions return, there will be nothing to be gained by its use for vessels of more than 1,000 tons.

More Comparisons

As the larger size of steamer is approached, the amount of steel required increases, until the weight of steel is about 75 per cent. the total weight of the hull. Great care has to be exercised in the placing of the reinforcing and in holding it in place while the concrete is being poured. Climatic conditions in some parts interfere with the procedure of the work, and there are more skilled men required than was at first thought necessary. The weight of the concrete hull is considerably greater than that of a steel hull of the same size, which means that the cargo carrying capacity of the concrete ship is less. Taking the standard 3,500 ton concrete ship constructed in the United States, some interesting comparisons are given. The dimensions are practically the same as a wooden ship of the same tonnage, namely: o. a. length, 281 feet 10 inches; length between perpendiculars, 268 feet; beam over shell, 46 feet; depth amidships, 28 feet 3 inches; draught, 23 feet 6 inches. The steel vessels built in Canada for the Imperial Munitions Board of the same tonnage are 261 feet o.a. long, by forty-three feet six inches beam, and 23 feet deep. That is twenty feet shorter, 2 feet 6 inches less in beam, and five feet less in depth. The following table is given in the report of the Concrete Ship Department, U.S.A., on the concrete ship:

Comparative Weights of Concrete Wood and Steel Vessels

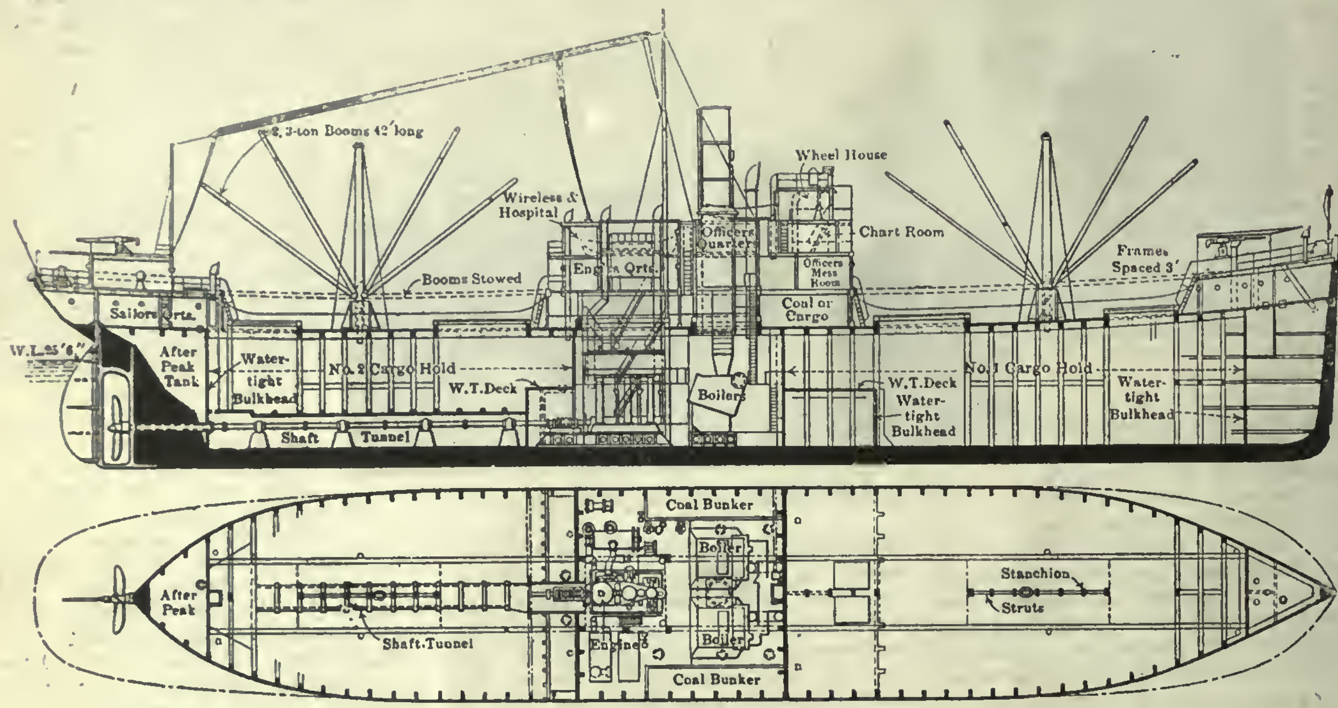
	Concrete	Wood	Steel
Hull	2,500	2 300	1,160
Fittings and equipment	191	191	180
Machinery	206	206	200
Margin	75	80	60
Ship (light)	2 972	2,777	1,600
Reserve Feed, Stores, Ordnance, Fuel	443	443	443
Cargo	2,760	2 680	3,057
Total deadweight	3.203	3,123	3,500
Full load displacement	6,175	5,900	5,100
% dw. to full load displacement	52	53	68.6

Can't Carry As Much

This shows that the earning power of the concrete ship of these dimensions will be less than that of the steel ship, directly by the amount of cargo less that she can carry. She will be more expensive to operate inasmuch as, if fitted with the same powered machinery she will require a longer time to make the same voyage, making the wages and victualling bill greater, or if fitted with propulsive power to make equal speed with the steel vessel, her fuel cost will be greater. Against this must be put the lower cost of construction. These vessels were estimated to cost $112.50 per ton deadweight, while the average cost for the steel ship was about $190 per ton d.w. The low cost is, in this case, due to figuring on a large number of vessels being made in the same yard, in which case the cost of shuttering, etc., would be much less, owing to it being used on several ships in succession. The cost would probably be closer to $150. In a paper read before the Institute of Naval Architects, Major Maurice Denny (member) gives some interesting figures; also a mathematical comparison of the steel and concrete ship earnings. He gives a comparison of a 375 ft. long steamer, of each type, of 9,900 tons displacement:

	Steel Ship Tons	Concrete Ship Tons
Displacement	9.900	9,900
Steel Hull	1,920	Steel 680
		Concrete 2,470
		3,150
Ship Light	2,890	4,070
Deadweight	7,010	5,830

We see therefore that in the 3,500 ton vessel the cargo capacity of the concrete hull is 90 per cent. of the steel, but in the larger vessel the percentage is only 83. So that in the concrete vessel, as the vessel gets larger, the cost



PLAN AND ELEVATION OF 3,500-TON CON CRETE SHIP.

of construction increases and the cargo capacity gets less compared to the steel hull. Major Denny then makes the following analysis of costs. Taking the steel vessel he allows the following values:

Bare hull	100
Machinery	50
Remainder	40
	190

Depreciation at 5% = 190x.05.
Other exs. = Z.
Profits at Y% = 1.9Y.
Earnings therefore are 9.5+Z+1.9Y.
The concrete ship will figure out thus.
Let X = cost of bare hull.
Machinery, etc. = 90.
Then X+90 = cost of ship.
Depreciation at 5% = .05 (x+90).
Other exs. = Z.
Profits at Y% = .01Y.
Then earnings = Z+(.05+.01Y) (X+90).

If deadweight is measure of earning capacity and concrete ship carries .83 of steel ship, then .83 (steel ship earnings) = concrete ship earnings.

÷ .83 (9.5+Z+1.9Y) = Z + (0.5 + .01Y (X+90).

$$\text{Solving } Z = 67.7 - \frac{1.7Z}{5+Y} \text{ or say } 68 - \frac{17Z}{5+Y}$$

A Comparative Table

From the above results Major Denny derives the following table for varying values of Y:

Y	X
0	68—3.4Z
5	68—1.7Z
10	68—1.1Z.
15	68—.85Z
20	68—.68Z

From this it is evident that under no circumstances must the cost of the bare hull of the concrete ship be more than 68 per cent. of the cost of the steel hull if the profits are to be equal. Major Denny then goes further in his calculations and shows that when freights are low the concrete ship cannot pay expenses. Allowing for the term Z a value of 50, which covers management, stores, wages, insurance, docking, repairs, coal, dues, loading and discharging expenses, etc., the figure of 50 is reasonable, representing 26 per cent. of total cost of ship per annum. Then by substituting the figure 50 for Z in the table above:

Y	X
0	—102
5	— 17
10	13
15	26
20	34

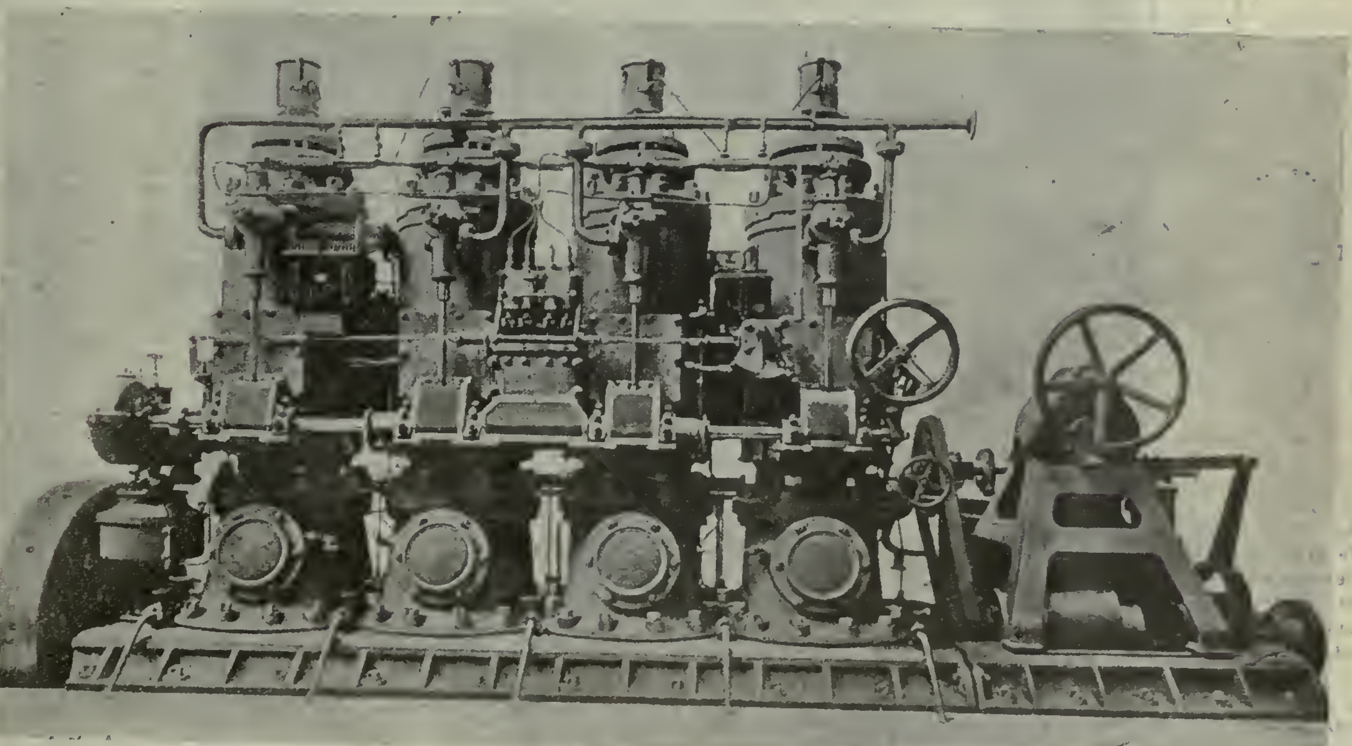
This shows that when the steel ship is earning 20 per cent. per annum, the concrete ship to earn the same dividend must have a bare hull cost of the steel ship. Major Denny points out that these figures are qualitative only, and are not advanced as a complete and detailed analysis of the problem.

Steel Will Be Lower

There is no doubt that the cost of steel will eventually become lower, and taking everything into consideration, the future of the concrete ship of large size is doubtful. For such vessels as canal barges, lighters, landing stages, etc., ferro-concrete should have a good field. It has some excellent points from the point of view of resistance to shocks, such as collision, bumping into wharves, and loading heavy materials from a height. Damage to concrete from blows is entirely local, and an instance is quoted of a concrete water tank in France, on top of a 75-foot tower, having the tower shot from under it, the tank sustaining no damage in the fall. If concrete ship designers succeed in bringing the weight of the concrete hull to approximate the weight of the steel hull, and still further reduce the amount of steel necessary, there will be a much better prospect of the large concrete vessel coming into general use. The performance of the vessels already built after two or three years' sea service will also furnish valuable information.

Conclusions

There have been many millions of dollars invested in the United States and Canada in plants for the building of ships and ship engines. The object in both countries was to help in the war, and further to develop a mercantile marine of their own. The United States feel that as a great nation, they should not be dependent on foreign ships to carry their cargoes, and that feeling has been more intense since 1907, when their fleet took its famous trip round the world. On that occasion they had to depend on British ships to supply them with coal. In recent days, more than half their army in France was carried over in British ships. Canada feels that to expand her trade she should have her own mercantile marine. Great Britain, during the war, has lent her ships to everybody that needed them, and concentrated on one object, winning the war, and in doing this has let her maritime trade connections slide.



DIESEL OIL ENGINE OF EUROPEAN DESIGN

Tyre Making a New Canadian Industry

DEVELOPMENT OF ARMSTRONG-WHITWORTH PLANT

FOR the second time in less than four years the firm of Armstrong, Whitworth of Canada, Ltd., have inaugurated a new industry into the activities of the Dominion. In the beginning of 1915 this firm, which is the Canadian branch of the parent company with factories at Manchester and Newcastle, England, commenced its initial enterprise in the newly built and modernly equipped plant at Longueuil, P.Q., opposite the Island of Montreal, and on the south shore of the River St. Lawrence. Anticipating future development from the growth of the business the original plans provided for buildings to accommodate additional expansion. The site selected offered excellent facilities for every phase of the company's activities, the adjoining town of Longueuil being conveniently situated for the accommodation of all the employees of the works, and with the north end of the property touching on the shore of the river. ample docking facilities are available for water shipments. Montreal, being an ocean port, aids materially in this respect, particularly for export business. The extent of the land controlled by the company approximates two hundred and fifty acres.

All the buildings are constructed of reinforced concrete with steel framework supporting the crane runways and the roof. The main building consists of a series of parallel shops and is so designed as to permit of additions to any or all of the bays without disturbing the present arrangement. Owing to the nature of the work engaged in, requiring many furnaces and ovens, and to maintain a free run for the crane in each main bay, narrow bays of about twenty feet wide are located between each of the main sections. To facilitate the handling of material when it is delivered to the plant, and for the shipment of the finished product, standard railway tracks are located through the center of each main section; local transfer being made on small trucks that operate on these standard tracks.

BATTERY OF SIX-TON HEROULT FURNACES

The pioneer work of this concern was in the manufacture of high speed and crucible steels, and high speed steel products such as taps, dies, punches, mining drills, milling cutters, twist drills, reamers, and tool steel bars, rolled and hammered into the various sizes and sections.

Casting The Ingot

The most recent developments in the activities of this firm is that of the manufacture of tyres for locomotive driving and truck wheels; this work will be supplemented in the near future by the production of forged steel wheels, the equipment for which is already installed. The process of making these steel tyres is not a very elaborate one, but the different operations are exceedingly interesting and the character of the work demands a thorough knowledge of the physical conditions of the steel under the treatment of the different furnaces and forming machines. The first detail in connection with the work of tyre making is the charging of the electric furnaces with the necessary material, which is composed of selected steel scrap.

The approximate time required to convert this scrap into molten metal is about 5 hours. Test pieces are made from the charge to see that the metal meets the required specifications, and

SHOWING LADLE IN POSITION, RECEIVING MOLTEN CHARGE OF STEEL

when necessary the desired alloys are added to change the molten metal to conform to the physical and chemical requirements. When all these conditions are assured the molten metal is poured into the large 10-ton ladle. When pouring the steel from the furnace to the ladle, the latter is located in an enclosed space at the front of the furnace. On the upper edge of these side walls are heavy steel plates that can be adjusted to protect the workmen from the excessive heat of the molten metal.

After the ladle has received the charge it is taken up by the crane and transferred to the ingot moulds that are generally arranged in parallel rows on the foundry floor. The ladle is of the bottom pouring type and the nozzle is kept as close to the mouth of the mould as conditions will permit. The moulds are shaped somewhat after the style of an inverted bowl, the size conforming to the weight of the metal required to make the tyre. In calculating the amount of metal required in the ingot, allowance must be made for the loss due to the scaling of the three reheatings, and the center that is removed from the bloom after forging to the desired thickness. The piping in the center of the ingot is not great, and owing to the fact that this portion is afterwards punched out, it leaves very sound steel for the tyre.

First Reheating

From the casting floor the ingots are taken to a specially designed low lift elevator located at the receiving end of the long continuous furnace; this lift is shown at the lower left corner of the plan layout. The elevator is operated by a small electric motor, and when the ingot reaches the top it is transferred across a short runway to the furnace loading platform. From this position the ingots are pushed into the continuous furnace by means of the specially constructed electrically operated pusher, which is controlled by the action of a screw feed located beneath the platform. This feeding of the ingots into the furnace chamber is in the charge of an operator whose duty it is to see that the ingots are placed in regularly. The burners for heating this furnace are so arranged that the heat of the chamber increases from 560 degrees at the feeding end to about 800 degrees at the discharge end. The floor of this furnace is set at an angle of about 10 degrees and the billets rest on two parallel pipes that run the entire length of the fire chamber, a distance of about 60 feet, sufficient to accommodate approximately 50 ingots of 750 lbs. each. The two pipes that form the runway are kept cool by the circulation of cold water. The ingots are discharged from the long section of the furnace down a short 45 degree incline, into the final heating chamber which has a capacity of half a dozen ingots. The time required for the passage of an ingot through this furnace is about three hours. In this and subsequent heating it is very essential that the temperature be even throughout, otherwise defects may develop in one or other of the forming operations.

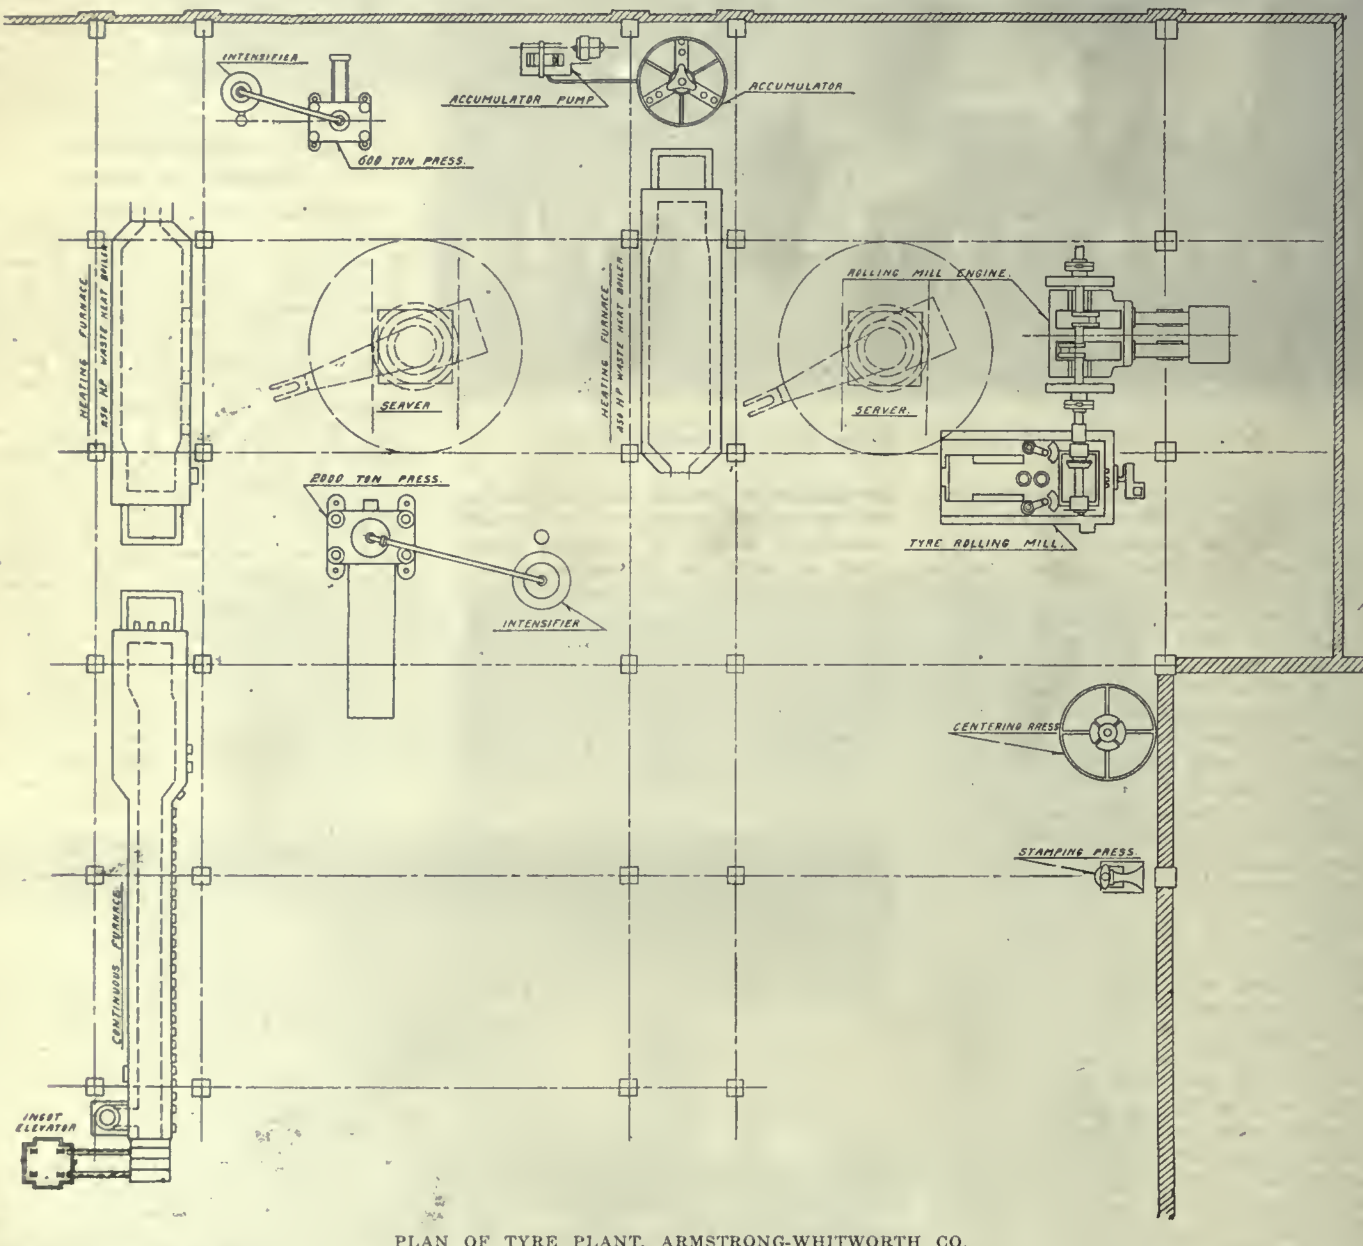
Forming the Bloom

When the ingot is raised to the desired temperature of about 1800 degrees F., it is removed from the furnace by means of a special server operating on the crane runway. This and the other servers, which were made by the Wellman, Seaver and Head, Ltd., of London and Bath, England, have a range of 360 degrees and can be operated to serve any of the furnaces or presses within its radius and the travel of the crane in either direction. The ingot or bloom is supported on the forked end of the server arm and then placed on the heavy anvil of the 2000-ton steam intensifier hydraulic forging press, which is located in the middle of one of the main bays. This press is provided with two anvils, either of which can be located in a central position for the operation desired. The breaking down anvil, which is made solid, can be revolved about its own center, this movement being necessary when extra large blooms are re-

TEEMING TYRE INGOT FROM LADLE INTO INGOT MOULDS quired. When the bloom is flattened to a thickness of 6 inches, the average width of a finished tyre, the press ram is raised and the bloom is grabbed by a pair of prongs operated by intricate levers supported in a framework at the side of the press. This appliance is hydraulically operated and can be seen at the lower left of the large press.

Piercing the Bloom

With the work held firmly in the prongs it is slightly raised from the anvil, and the movement of the lower slide brings the anvil that carries the piercing die into the central position below the ram. The bloom is then dropped on the die and the anvil brought out again so that the piercing punch can be placed in position. This consists of a steel block 10 inches in diameter and is located solely by the eye of the man in charge of the press. The anvil is returned beneath the ram and the lowering of the same forces the punch through the bloom, and the former and the piece punched out, passes through the die. The bloom is again supported by the side arms while the main anvil is brought below the ram, when the bloom is again flattened. It might be mentioned that the control and operation of the press and other mechanisms is in the charge of one man.



PLAN OF TYRE PLANT, ARMSTRONG-WHITWORTH CO.

Rough Forging to Shape

The pierced bloom is now ready for the second reheating, which is done in a furnace located at the discharge end of the continuous furnace and between the breaking down press and the one used for the becking of tyre. The pierced bloom is again brought to a temperature of about 1800 degrees F. and by means of the server is taken from the fire and located on the horn of the 600-ton steam intensified hydraulic becking press. The work performed on this press consists of a series of pressures on the outer diameter of the bloom that in a short time produces a ring roughly resembling, and of a diameter about three or four inches less than the finished tyre. The horns used are of different diameters to suit the size of the tires being made, and are located in a housing with the working surface about four feet above the floor level. The horns are placed at an angle of about 15 degrees and the face of the pressure block, that is fitted to the press ram, is at a corresponding angle. This inclination assets in the formation of the flange and maintains the inner face against the shoulder of the housing, this latter action being further aided by means of a long bar suspended in a notched cross bar fixed to the two-side pillars of the press. This bar is operated at the outer end by two workmen, as considerable pressure is required to keep the ring in position. Following each successive pressure or swage, the ring is revolved through an angle of approximately 15 degrees. This operation is controlled by one man using a long bar fulcrumed in a notched bar laid on two supports and extending across the front of the press about two feet above the floor. A series of notices are made on the top of the bar to accommodate the different dia-

2,000-TON STEAM INTENSIFIER FORGING PRESS, FORGING INGOT INTO TYRE BLOOM

meters. It might be stated that forming blocks of any desired shape may be adopted to suit the work in hand. The time required to shape the tyre at this operation varies from 3 to 7 minutes, according to the size and weight of the tyre. The work on this flanging press roughly rounds the tyre into shape, but before it is placed into the third reheating furnace it is placed back in the large press and again flattened.

Final Rolling Operation

The last heating of the tyre is performed in the furnace located in the center of the department and this furnace is open from either side, so that the righly formed tyre is placed in on the one side and removed from the opposite side.

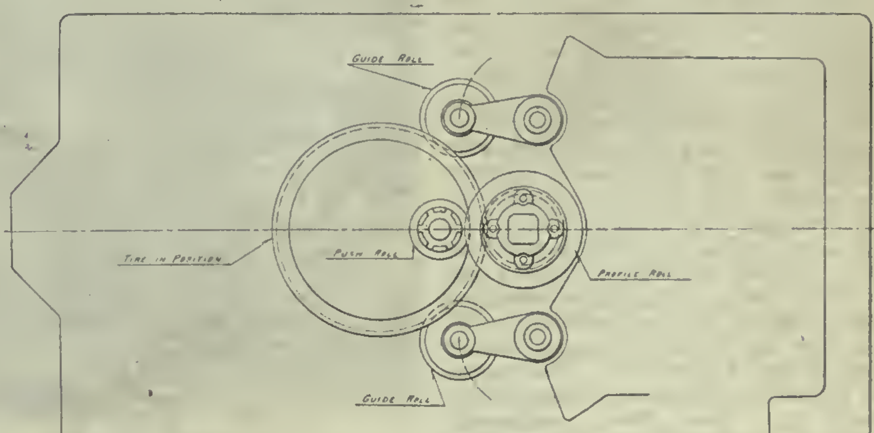
The heated ring is again taken up by another mechanical server and removed to the rolling mill, where the final operation is accomplished. The heavy duty engine that drives this mill is of about 1500 h.p., and was constructed by the International Engineering Works. This unit is directly connected to the Morgan tyre rolling mill. In this operation of rolling the tyre to the finished size and shape it is imperative that the steel be uniformly heated to assure a satisfactory product. Immediately the heated ring is placed over the push roll, the latter, which is operated by means of a hydraulic cylinder beneath the machine, is forced up and against the inner edge of the ring and in turn presses the ring into the profile roll which remains in a fixed position. The operating cylinder is 18 inches in diameter and with a working pressure of 1500 lbs. per sq. in., the pressure exerted on the tyre for the rolling process is upwards of 100 tons. Guide rolls are located on either side to steady the work while in action and to round up the tyre to the desired shape and concentricity. During the rolling of the tyre running water is permitted to flow on the work from between the guide rolls and the profile roll, and in addition to this a man is employed in directing a stream to the inner surface of the ring, or to such places as are desired. When the required size has been obtained or nearly so, the pressure is steadily maintained, but no more water is alowed to pass into the cylinder, so that the push roll remains in the one position. It is necessary to do this while excessive heat remains in the steel, as the contraction would otherwise be too great and when the tyre cooled off it would probably be below the desired size.

The gauge adopted for determining the finished size is quite interesting and is so accurate that during the final revolutions in the rolling of the tyre it does not show the least variation from its indicating point on the graduated gauge. The construction of the gauging attachment is such that the indicating point is always in the same position, irrespective of the size of the tyre being made, and is always within the direct line of vision of the control operator. The concentricity of the tyre at this point is virtually perfect. When the tyre begins to turn black the pressure is removed and the tyre taken out of the machine and placed to cool. The shrinkage on a 32-inch tyre after being removed from the rolling mill will be about ½ inch, and in the case of a 74-inch tyre the shrinkage will be approximately 15-16 inch. For machine finished tyres the amount of stock left on the inner and outer diameters is about 3-32 of an inch.

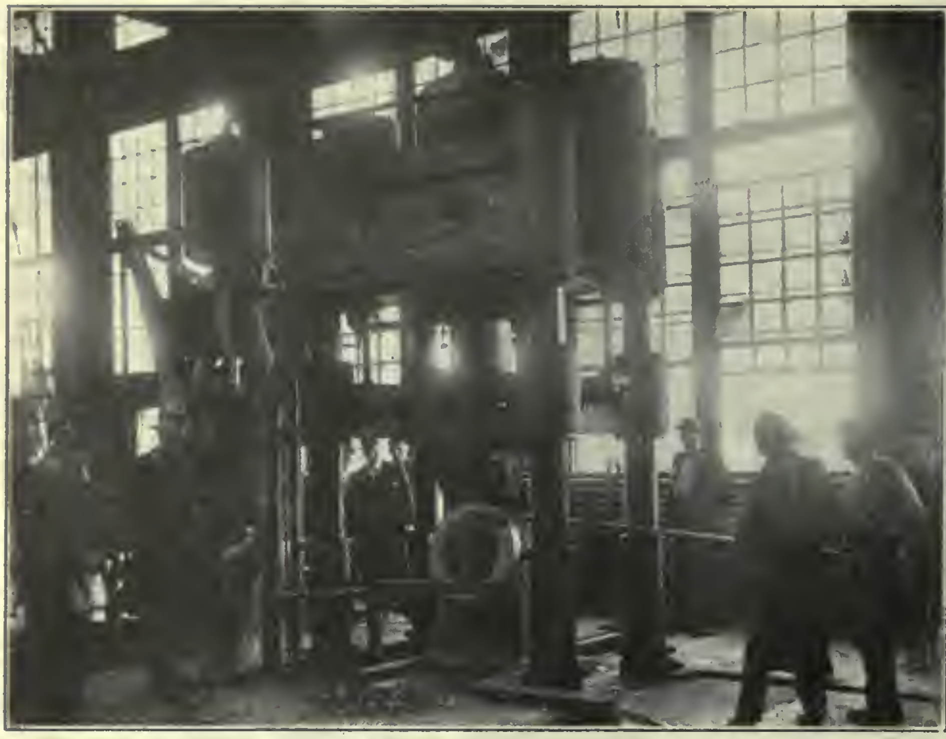
Heating With Powdered Fuel

A feature that deserves special mention in connection with the operation of the furnaces is the utilization of powdered coal for fuel. The plant for this purpose was installed in 1917 and the system has given such good results that it has been adopted for use on the majority of the furnaces in the plant. Experiments with powdered fuel on the two 18-ton basic open hearth furnaces recently installed, have proven its adaptability in this respect and its permanent application is now being considered. The plant that has been constructed for the purpose is capable of producing five tons of powdered coal per hour. The system is divided into three separate circuits so that fuel can be supplied to or cut off from any one department without affecting the supply to the others. The operation of the system is virtually automatic in its action, the powdered fuel being in continual circulation. The cutting out of any of the furnaces in a department does not affect the distribution, as the operation of the air control valves regulate the speed of the small motors that drive the fans for blowing the fuel through the delivery system.

As in the initial activity of this firm this latest enterprise of tyre and forged steel work marks a new epoch in the steel industry of Canada, and likewise represents anothed blow to German supremacy, as the majority of Canadian



PLAN SHOWING MACHINE FOR ROLLING TYRES.



6,000-TON STEAM INTENSIFIER HYDRAULIC BECKING PRESS, FORGING BLOOM INTO ROUGH OUTLINE OF TYRE

locomotives and cars, before the war, were running on Krupp tyres. Prior to the establishment of the plant of Armstrong Whitworth the supply had been coming from the States, while now the Canadian railroads are assured of ample home made tyres for all their requirements.

To the establishment of the plant the credit is largely due to the efforts of Sir Percy Girouard, K.C., the president of the Company, and G. G. Foster, K.C., the vice-president, while the successful development to its present efficiency is due to M. J. Butler, C.M.G., the managing director, and his able assistants Lawrence Russell, assistant general manager, and H. Johnson, the general superintendent.

METHOD OF SYNCHRONIZING ELECTRIC MACHINES

By M. M.

A new method for synchronizing electric machines, is a development from one already used. It consists in connecting choking coils in the alternating current leads, bringing the machine to the neighborhood of synchronism by an auxiliary machine, and then gradually exciting. If the choking coils are suitably designed the machine will fall into synchronism after one or two oscillations. When this has taken place, the choking coils are short-circuited, which gives rise to a considerable current rush. It is also possible to use an induction motor for starting, with its windings connected in the place of the choking coils. This causes the reactance to decrease as the machine starts up. Even then considerable rushes occur when the induction motor is short-circuited. The reactance of the serious choking coils is decreased automatically and gradually, to such an extent that practically no current rush takes place when they are short-circuited A further advantage of the method lies in the freedom of choice of the type of the auxiliary motor. The reduction of the reactance of the choking coils is affected by superposing a direct current field upon the alternating current field. Direct current excitation of the choking coils may be drawn from the commutator of the rotary converter that is being started up, and the choking coils may be inserted either on the primary or on the secondary side of step-down transformers. It is only necessary to use a choking coil in one of the phases in a three-phase machine. The direct current excitations may be also derived from any separate source. The choking coil may be designed with three limbs, the outer ones carrying the alternative current windings, and the middle one the direct current windings.

PRINCESS SOPHIA WRECK

We are informed by Marine Department officials at Ottawa that a formal investigation into the loss of the Princess Sophia will shortly be held. It is understood that the investigating commission will be composed of the Admiralty Judge in British Columbia, assisted by two assessors, and will be appointed immediately by the Dominion Government.

Washington, D.C.—The reinforced concrete steamship "Atlantus," 3,500 tons carrying capacity, was successfully launched 9 a.m., December 3, at the yards of the Liberty Shipbuilding Co.. Brunswick, Ga.

The "Atlantus" is the first of the concrete ships contracted for by the U. S. Shipping Board Emergency Fleet Corporation, to be finished. Sister concrete ships, as well as a number of concrete ships of 7,500 tons capacity, are being built in the yards of the Liberty Shipbuilding Co., and in four other yards established by the Government exclusively for concrete ship construction.

TYRE ROLLING MILL, LAST OPERATION COMPLETING TYRE

SOME MEANS MUST BE FOUND TO KEEP THE CANADIAN SHOPS BUSY

The Smaller Organizations Should Receive Co-operation and Support Just Now to Help Them Over a Trying Period.

By C. GRAHAM DRINKWATER, Vice-President Canadian Fairbanks-Morse Co.

I see no reason why Canada should not get her share of reconstruction requirements in Europe and at the same time look after her own trade.

The larger industries will take care of themselves, but the smaller manufacturers will unquestionably need assistance in securing orders. The Imperial Munitions Board solved this difficulty in so far as war materials were concerned, and we confidently look to our newly appointed Trade Commissioner to render similar assistance at this time. Such a Board with Sir Charles Gordon at its head can be of invaluable service to Canada. We congratulate the Government on its foresight and trust some business will be forthcoming shortly which can be distributed among our various miscellaneous industries, and help hold our splendid munition organizations together. Otherwise we are facing a period of readjustment, not for big production, but for production on a much reduced scale from the activity of the past four years, and this means labor unrest and small profits from which to pay taxes.

Canada has shown that she has tremendous manufacturing ability, and some means must be found to keep her at work.

THE ADVENT OF A NEW SPIRIT IN INDUSTRIAL LIFE IS APPARENT

By A. L. HAAS

INTENSIFIED by the circumstances of war, change in every direction is rapid. Normally such changes as have been witnessed in the past four years would take generations to effect. Among much that is regrettable and pernicious war has at least one benefit in that it hastens material progress while destroying much that makes life worth living.

Evolution proceeds usually by tentative and slow stages, but the furnace of conflict has a forced draught and while consuming much that can ill be spared does quicken change and accelerate progress in certain directions. Nowhere is this more manifest than in mechanical matters which are the outstanding feature of the last decade and more especially the last four years have seen an unparalleled alteration. Whereas before August, 1914, the machinery salesman had to make great exertions to supplant out-of-date machines by modernized and improved alternatives, to-day the very people whom it took months to convince are themselves seeking diligently for new plant, price being quite a secondary consideration. In place of the salesman trying in every way to convert the customer, the latter now chases the salesman who nonchalantly makes evasive promises.

The reaction of a restricted labor market shows in many directions.

The discontent, murmuring, high wages and independence is one feature which receives much publicity; the other feature is the quickened appreciation of new process, improved method, more efficient machines, the fresh viewpoint on the part of those responsible for production. This has received less notice, but is full of future promise.

The conditions noted are mutual in their effects, high wages, better conditions, plentitude of work, improved mechanism and method are interdependent variables in the formula of production. All previous beliefs have received so rude a shock that greater discrimination in finish, relative accuracy, separation of process, revaluation of relative skill have received extended attention.

The change in attitude is not confined to any one section, it is common to all. Owing to expansion the former private now holds a more responsible commissioned rank in the industrial army, while the opportunity to assume responsibility at an early age has given exceptional chances to youth.

This last factor is of immense importance, for in many directions it has freed industry from the incubus of the experienced, but hide-bound individual tied by precedent and tradition and averse to change. Whole industries have sprung up where the most experienced are still youthful, judged by any former standards.

The new spirit in industry is shown by quickening progress and expansion of the individual; former captains of a hundred now administer thousands and the severe tuition of a time of stress is leaving marks which will influence the future.

It is increasingly evident that industry generally has to be more co-operative in the future, less individualistic. All the reconstruction proposals place this beyond dispute. Co-operation involves everyone affected and it is impossible unless a common atmosphere favors its continuance.

More individual responsibility is required from below as well as greater tolerance from above. The spirit of identity and association to a common end cultivated in school, in national and municipal affairs, and more especially in the realm of sport, form the precedents for the hope of those most interested.

It is to be regretted, therefore, that before trial has been made or a fair chance afforded to the Whitley proposals in England, leaders of labor thought, should have seen fit, to stand aloof and indeed, forbid those under their charge from participation in any scheme of the kind.

To frustrate or afford no trial to a new idea is fatal to progress. Constructive attempts to stabilize industry are not ordinary happenings, for in the ultimate analysis it is ideas which rule, not mere expedients. It is rival ideas which cause disintegration, and the new idea, which is the logical fresh step on the ladder of evolution, cannot be frustrated with impunity. It will eventually defeat any mandate like the tide on the shore.

There is much troublous water to steer through in industrial matters, but the new spirit of high endeavor should suffice to avoid the difficulties. In fact the new spirit is apparent in so many directions that it almost amounts to a new industrial renaissance.

Seattle.—The wooden shipbuilding industry of Puget Sound delivered up to the end of November thirty carriers of 102,600 tons deadweight capacity. An additional 35,000 tons will be delivered by the wooden shipbuilding yards this month, giving them a total of 137,600 tons by the end of the year.

The following list of plants and their tonnage output has been issued by the Northwestern Shipbuilders' Association:

Plant	Ships	Ton'ge
Albina, Portland	7	25,600
Ames, Seattle	10	88,400
Columbia River, Portland	10	88,000
Duthie, Seattle	12	105,000
Northwest Steel	16	140,800
Seattle Construction, Seattle	5	40,500
Skinner and Eddy No. 1, Seattle	27	237,800
Skinner and Eddy No. 2, Seattle	2	17,600
Todd, Tacoma	7	52,500
	96	796,800

The Machine Tool Dealers of Toronto

T. A. Hollinrake, President A. R. Williams Co.

ONE OF THE PIONEERS OF THE MACHINERY BUSINESS

—By A. R. K.

PERHAPS it is only fitting and proper that an industrial centre such as Brantford should send out a lot of men to occupy responsible positions in the industrial and machinery world. Brantford has turned out a number who have come pretty well up toward the top of the heap in various lines. The Telephone City claims T. A. Hollinrake as one of its native sons. In fact, the family home is still there, and Mr. and Mrs. Hollinrake, Sr., are both living.

T. A. Hollinrake is now president and general manager of the A. R. Williams Machinery Co. He first became connected with the firm because the late A. R. Williams considered there was more opportunity for two firms to centralize their efforts than remain as competitors. It came about this way:—T. A. Hollinrake and Robert Kerr established the Canada Machinery & Supply Co. in Brantford about the year 1890, and were doing a nice business in that line. Mr. Hollinrake had a varied knowledge in machine shop and other similar lines, while his partner, Mr. Kerr, had graduated from the Waterous plant, where hundreds of first-class mechanics have entered as apprentices. And so it was that in the year 1894 the Toronto and Brantford firms were merged, taking the name A. R. Williams Machinery Co. Mr. Williams was president, Mr. Hollinrake vice-president, and Mr. Kerr still retains a place on the board of directors.

T. A. HOLLINRAKE
President and General Manager of the A. R. Williams Machinery Co., Ltd.

Mr. Hollinrake is pretty well tied down by the amount of material passing through the Toronto office, but if he had the chance to pick and choose the chances are that he'd get out and sell machinery. For a long time T. A. Hollinrake was known personally from Halifax to Vancouver. He went out after business, and he got it. He knows the lumber country of the North and West, the mining country, the lumbering camps of British Columbia and the mills of New Brunswick. As a matter of fact, men in the business have told me that T. A. Hollinrake went through the Crow's Nest Pass in Southern British Columbia ahead of the C.P.R. Crow's Nest line. He was selling sawmill machinery to Sandy McDougall at Fernie before the pioneers there had decided to call the main street of the town Victoria Avenue. Nor can it be said that he picked the easy trips, either. In the early spring he used to leave Toronto on the long Western trip. In those days there were many districts that had trains only two or three times a week, and selling machinery then meant hard work and lots of it.

But to get back to the business. In 1894 the newly-formed company built the big warehouse and shops on Front street. And just here it might be mentioned that the entire staff in those early days numbered only 35, as compared with something over 200 at the present time. When the Front street property was expropriated for the new Union Station, the Cobban property was purchased on the Esplanade for shops and warehousing purposes, and the head offices, showrooms and supply departments were located in the old Copp-Clark premises, right opposite the new Union Station, which were purchased by the A. R. Williams Co. At that time the only branch of the business was in Montreal.

The growth of the business made it certain that it could not be handled from Toronto any longer. Hence the Winnipeg branch was opened in 1902 to look after the territory between there and the coast. Three years later the Vancouver agency was established, the lines handled there having largely to do with saw mill machinery, log engines and boilers, mining machinery, etc. From this branch an export business with the Orient is conducted. In the East the St. John, N.B., business was established in 1910. An American branch in Buffalo, operating under the name of the A. R. Williams Machinery and Supply Corporation, was opened in 1917.

Speaking to the writer only a few days ago, Mr. Hollinrake expressed himself as optimistic regarding the outlook for 1919 business. That was after returning from a conference of all the Canadian managers at Montreal. "What did we do there?" said the president, in answer to a query. "Well, we sold reconstruction to each other. If the Governments go ahead and make their adjustments quickly, trade should start and move very soon. It would be good policy to remove the traces of war from the machine tool business as soon as possible."

"And how about export?"

"Well, this country ought to be able to get into foreign markets. Just now we are doing a nice business with Japan. We have found it possible to meet the prices of other countries in open competition. If there's one thing that is holding back Canadian trade abroad it is a lack of knowledge of foreign countries regarding this country and its products."

On the death of A. R. Williams about two years ago, Mr. Hollinrake, who had up to that time been vice-president of the company, became president and general manager.

The Machine Tool Dealers of Toronto

Fred W. Evans, Canadian Fairbanks-Morse

HAS DEVELOPED BIG BUSINESS IN TORONTO FIELD

—By A. R. K.

IF one were to inquire for any standing instructions that might be given to the Toronto staff of the Canadian Fairbanks-Morse, it would be a safe guess to say that they could be summed up in two words, "Don't Bluff."

Not that I've ever seen any code of rules posted up around the place, but it's there as plain as any unwritten law can be. And, moreover, one of the company's salesmen told me that such was the sum total of the instructions that he received from the Toronto manager when starting in this territory: "You have a general knowledge of the machine tool trade, but remember, you are going out to meet and deal with specialists in a dozen different lines, and each of these specialists knows his line thoroughly. Never forget that."

But this story isn't so much about the Canadian Fairbanks-Morse Co., as about the Toronto manager, Fred. W. Evans. At the age of 33 he's one of the best known and most successful men in the machine tool business in Canada.

It can't be said that he planned a career for himself in this line. In fact, there's a story in machinery circles that he did, in the truest sense of the word, "break" his way into the business. Some folks set out and work along straight lines to a given point, but the most of us don't, and F. W. Evans belongs to the "most of us."

The old whirligig of fate has a habit of taking people unawares, pitchforking them here and there, and picking out round men for square holes. And after it's all over these men set to work to finish the job that fate started by changing the square hole or fitting themselves to it.

Mr. Evans is a product of Montreal, born there in 1885. He received his early education in the public schools in that city, and on leaving school entered the Grand Trunk shops at Montreal.

He didn't stick. In fact, he found that the opportunities he was looking for were not in that line. And so it was that, after a course in business college, he entered the office of Fairbanks-Morse as a clerk in 1904. And here's where he "broke" into the machine tool line.

In the Montreal office was a particularly fine Brown & Sharpe miller, and Evans had often admired the thing and had more than once given a turn to the feed levers. This turning process was continued to such an extent that one day the limits of the machine were exceeded and something snapped. At that time Mr. Rudel, now of the Rudel-Belnap Co., was in charge of the machine tool department of the Fairbanks-Morse Co., and that particular B. & S. miller was some pumpkins in his eye. So when he saw his pet hobby broken he drew up the siege battery to shell out the victim. After the bombardment had produced no results, the boy Evans walked into his office and told how the B. & S. machine had been put on the blink. But Evans wasn't canned. In fact, a strong feeling grew up between Rudel and the clerk, and it wasn't a month after before he had taken him into the machine tool department. From then on promotion came quickly. He was assistant manager, machine tools department, 1909-1910; manager of the department, 1910; manager of the Winnipeg branch, machinery department, 1910-1914; manager of the machine tools department for Canada, Montreal, 1915; transferred to Toronto, 1915; general manager of the Toronto business since 1916.

FRED W. EVANS

Toronto manager of the Canadian Fairbanks-Morse Co., Ltd.

Particularly during the duration of the war has the Toronto business of the Fairbanks-Morse Co. developed. I happened to mention this fact to Mr. Evans one day, but he simply admitted the fact, and stated that he was the victim of favorable circumstances. When it comes to talking, he can talk business and trade, bowling, motoring—yes, and a bit of Liberal politics as well—but when it comes to talking about F. W. Evans, well, as a space-filler, he'd starve.

Speaking of business, Mr. Evans has strong views, and these are also held by his company. "Just now we are receiving a number of requests from all over the country to buy in equipment that has been used in shell shop work. We won't touch it. Our policy has been all through to encourage the sale of new machinery. It's better all around. We'd rather do less business for the present than be very busy taking in second-hand machinery. Selling new machinery forms the basis for good, clean, square business with very little come-back to it."

Since coming to Toronto, Mr. Evans has taken an active interest in several undertakings. He is a member of the Canadian Manufacturers' Association, Toronto Board of Trade, and of the Ontario, Rotary and Empire Clubs. In 1910 he was married to Miss Edna Hurd, daughter of Dr. J. E. Hurd, Toronto. The Evans home is 19 Oakmount Boulevard, Toronto, where two young men rise up and salute F. W. as "dad."

The Machine Tool Dealers of Toronto

The Garlock-Walker Machinery Company

TWO SUCCESSFUL SALESMEN JOINED FORCES IN 1916

—By A. R. K.

LANDING in New York at the age of 14 with $1.48 in his pockets, reads something like the start of a romantic business career. I don't know if the amount is correct to the cent, but it's pretty close to it. Just how he got along for the first few weeks or months I've never heard, but he always put in a lot of spare time studying, and it was not very long before he was fairly well versed in shorthand. In fact, shorthand, and a desire to some day study law, seems to have been the tandem in which most of young Garlock's ambitions were riding at that time.

That's a few years back now. William Garlock was born in Oswego, on April 17, 1882. He's now president of the Garlock-Walker Machinery Co., Toronto, one of the firms that has forged ahead rapidly during the past five years. But just before we forget it, there's a story concerning those early New York days that deserves printing. The chances are Mr. Garlock will wonder where CANADIAN MACHINERY heard of it. But here's the story as I heard it:—

One of his first positions was as stenographer in an office. Wages $5 per—board $4.50 per—balance 50 cents per—week. The "boss" intimated that he was going to Denver for a couple of weeks or so and Garlock, Jr., was to look after things in general. In fact, he was at the office with the boss the night previous to his departure getting final instructions. The stenographic department of the office (consisting of W. G.) turned up as usual the next morning, and found things dull. After lunch—shoebox kind—things were likewise dull, and the stenographic department of this New York office decided that it was time to act like any other real office man. So he dusted off the boss' pet sign and got it ready for action. It read "Out—Back at 5.30." So without any more preliminaries the sign was displayed on the outside of the office door. We've clean forgot what the score was at the ball game that afternoon, but 'long about 5.50, true to the promise on the shingle, Garlock, Jr., returned to his place of business, just to make sure that it hadn't departed. But there had been some tinkering with that billboard in the meantime. The hang thing had been taken down, the door was open, and the boss was on the job. The $5 a week job passed to other hands.

A strong preference for studying law probably turned him to his next position with a New York legal concern. By that time he was an expert stenographer. That was, if my dates are right, about 1898. For six years he worked as law clerk, hunting up evidence and securing all the necessary preliminary training for the legal profession. In fact, if he were to leave the machinery field now, my best guess would be that he'd turn to law even yet. A breakdown in health settled this, however, and in 1905 he entered the sales offices of the American Woodworking Machinery Co. This company, although located at Rochester now, was then in New York. There wasn't much spare time in those days. Mr. Garlock taught shorthand three nights a week in a Y.M.C.A. night school—the other three he studied and tutored with university students. Promotions came rapidly, and by the time he was ready to open the Canadian field for his company, he was sales manager of the eastern division, in charge of a sales staff covering 15 states.

WILLIAM GARLOCK, JR. ALBERT B. WALKER

It was on the first of May, 1913, that Mr. Garlock came to Toronto to open the Canadian branch of the American Woodworking Machinery Co. The results were not entirely satisfactory, and the company decided to close the Toronto office. William Garlock did not see things that way, and he decided to stick on his own account. When Canadian firms started to make munitions he turned to metal working machinery as well. His first order was for $100,000, and he at once placed his orders mostly with American concerns. Two weeks later the order was cancelled. It was up to Mr. Garlock to cancel also or sell. He decided on the latter course. He had sixty days to swing the deal. Strenuous days, those, but to make a long story short, he sold and delivered the whole consignment.

It was on the first of January, 1916, that the firm Garlock-Walker Machinery Co. was formed. Albert B. Walker, known to many in and out of the trade as "Doc," took over the metal working end of the business. And he comes honestly by that name of "Doc," for he practised medicine for five years in Michigan, after graduating at Detroit. Mr. Walker retains a strong liking yet for the profession, but it was poor health that forced him out. As a matter of fact, I belive I'm right in stating that he volunteered for service in the recent war as a doctor with the U.S. Army, but was not called.

Mr. Walker is an old Toronto boy, but the family moved to Galt, where he went as far as matriculation in school work. Entering the Goldie-McCullouch shops when David Hastings, now general superintendent, was foreman of the machine shop, he served his apprenticeship as a machinist,

The Machine Tool Dealers of Toronto

A. E. Juhler of the Rudel-Belnap Company

STARTED IN MACHINE TOOL BUSINESS IN EUROPE

—By A. R. K.

REFERENCE is often made to firms that have "long and honorable careers." Evidently this country is not old enough yet to boast of the real thing. Perhaps we imagine that some of our concerns that have been in business for fifty or sixty years have a right to be thus listed, but when other records are looked into, this young country's record looks of the amateur type when it comes to years.

For instance in Copenhagen there is a firm handling American machine tools and supplies under the name of V. Lowener. That house has been established for over 250 years. They command a wide patronage covering practically the whole north of Europe. It's hard to say what changes the war has made in this regard. But to get down to the story. Some thirteen years ago a young American became connected with the firm, after having spent some years on the continent for the Bethlehem Steel Corporation. He's a resident of Toronto now, living at 89 Delaware Ave. His name is A. E. Juhler, Toronto manager of the Rudel-Belnap Machinery Co.

If my information is correct, Mr. Juhler is a native son of some spot in Southern Ohio—as a matter of fact it's doubtful if the place is recognized by the map makers. It might be said that his whole life has been so far spent in work closely allied with machinery, engineering and allied projects. Graduating from Lehigh University in 1892, he had hardly ceased being a sophomore when he got out and went to work to apply what he had soaked up at school. Mr. Juhler had specialized in factory engineering, which included mechanical lines and an extra amount of chemistry just to keep him busy. He didn't start with any two by four concern either, but hitched up to the Standard Oil Co. in the construction and operation of plants, being first located at Whiting, Ind. His work with the Standard Oil Co. also took him to Europe a number of times.

A. E. JUHLER
Toronto Manager Rudel-Belnap Machinery Co.

It was in the year 1903, that Mr. Juhler went with the Bethlehem Steel Corporation, going to Europe exploiting the Taylor-White tool steel patents. This took him through Northern Europe time after time, and brought him into very close contact with the mechanical developments and ideals of nearly every country on the continent. The introduction of these tool steel patents, and their adoption in more centres naturally led to a realization of the need for better machine tools with which to use the high speed steel, and it was really from this that Mr. Juhler entered the machine tool business with the V. Lowener Co., at Copenhagen, making a specialty of American machine tools. The writer once discussed with him the various points where Europeans excelled and failed in the production of machine tools, and it was apparent that he had seen a lot and remembered most of it. In fact, he had quite an admiration for some of the wood working machinery that was turned out in Sweden, claiming it to be superior to anything that was being placed on the market at that time.

Returning to this side of the Atlantic, some 12 or 13 years ago, Mr. Juhler was identified with various machinery houses and engineering concerns, living at Montreal, Hamilton and in Toronto for the last six years. He came here to establish the Toronto branch of the Rudel-Belnap Co. But he was in Canada some years before his connection with this firm. It was the building of the Imperial Oil Co. refineries at Sarnia that first brought him to this country. There's one thing worth mentioning in connection with this contract. The cutting up the holes for the tanks was in charge of Wm. Stokes, who shortly afterward had charge of most of the actual drilling and digging of the St. Clair tunnel, under the direction of the engineer, Mr. Hobson, father of Mr. Robert Hobson, now president of the Steel Company of Canada.

Since the opening of the Toronto branch, Mr. Juhler has met with success. There has been a lot of business handled in the rather modest suite of offices on Adelaide St. West. Apparently they have handled a select line, as reports at the head office in Montreal will show that there hasn't been a dollar lost in bad accounts at the Toronto office in six years.

"We have very clearly defined policies," remarked Mr. Juhler, "and we try to adhere very closely to them. The lines we handle are controlled by us here. If a customer wants a lathe for instance, we can present only one make to him. If he wants a grinder or a drill the same thing holds true, likewise with a planer. We find that specializing in this way is quite satisfactory. Our selling prices, also, are limited by the selling price at the factory. We have never made a practice of going into used machinery. The war period brought us a lot of very satisfactory business, both in Montreal and Toronto."

Like many another enthusiast in his business, Mr. Juhler enjoys the day when he finds it possible to get away from the office and get after orders outside, and one of his "regrets" at the increase of business is that it is making it necessary for him to spend more of his time in his office.

THE GARLOCK-WALKER MACHINERY CO.

Continued from page 768

afterwards gaining experience with their sellin~ force. It was shortly after this that Mr. Walker started the study of medicine, in the summer months working on the sales staff of the H. W. Petrie Machinery Co. A siege of sickness followed his five years' medical practice in Michigan, and he was forced to abandon this life. Returning to Canada he joined the A. R. Williams Machinery Co., going from there to the Canadian Fairbanks-Morse Co. For eight years prior to forming his present partnership he was with the H. W. Petrie Co., having spent in all some 15 years as a machine tool salesman.

Mr. Garlock, the president of the firm, believes the machine tool dealers should work much closer together, especially at present. Speaking to CANADIAN MACHINERY on this point not long ago he said: "It would be better for the dealers to have a uniform policy regarding the disposal of shell plants. Many purchasers now will meet dealers with a proposition to take over a certain amount of their shell shop equipment on the sale of new goods, and if the dealers would arrive at some definite understanding it would do much to simplify the whole situation."

Mr. and Mrs. Garlock and daughter live at Ernscliffe Apartments, 197 Wellesley St., Toronto. Mr. Garlock, in spare time, fishes and plays golf, although fishing for business has been his chief occupation for the last four years.

THE PROBLEM OF THE SMALL SHOP WILL NEED CLOSE ATTENTION NOW

By T. S. Worthington, Montreal

RE-ESTABLISHMENT of normal activity during the post-war period is already engaging the attention of politicians, business men and captains of industry. The share Canada will have in the reconstruction programme is, as yet, very uncertain but depends in no small measure on the capacity for prompt action in securing for herself some of the business she is justly entitled to, but for which she will have to scurry in common with other countries.

What Canada has achieved in the production of munitions and the manufacture of different classes of material and war equipment, is ample evidence of her ability to take on and carry to a successful conclusion almost any line of industrial enterprise. Co-operation of the Government and representatives of large commercial and manufacturing interests is even now at work to obtain for Canada some portion of the rehabilitation activities that are absolutely essential to European prosperity.

It is beyond question that this country will have energetic competitors for a large proportion of this prospective foreign trade, and it is imperative, therefore, that every effort be made to advise and influence the European buyer that Canadian industries are in a position to supply virtually every need in the rebuilding requirements of the various manufacturing and mining centres destroyed, or other devastation by the unprecedented destructive warfare of the past four years.

One of the features of after-the-war development, or even continued activity, that has probably received little attention or consideration, is the outlook of the host of small machine shops and manufacturing plants the increasing co-operation of which has made possible the remarkable achievement in shell production of many of the larger industrial establishments. What will be the position of these small plants during that period of reconstruction that is certain to follow on the heels of the recent war, the destructive agencies of which have never been equaled in the history of the world? Will these small plants be isolated from the opportunity to participate in this work of reconstruction? Will the initiative of the larger interests react on those who are apparently dependent on the growth of the big concern, or will the little fellow reach out and secure for himself some of that European business which will go to the parties first in the field and in a position to perform the work?

Different agencies are now at work both in England and on the Continent to obtain business for Canadian industries. Many of these will be instrumental in landing their objective, but no assurance is given that the little fellow, who has faithfully performed his allotted task in the heat of war emergencies, and who may now be patiently waiting for some portion of foreign business, will share in any orders that may be placed here for European markets. The necessity for widespread distribution of contracts after the war will be less pronounced than when every available plant was working on war essentials, so it is not unlikely that fewer subcontracts will be the order of the day after peace is finally restored. It therefore seems imperative that the smaller interests should leave no stone unturned that might unearth some means of maintaining their plants in a healthy working condition.

A proposition that has been advanced by one of the business men of Montreal, and one that is interesting a number of smaller manufacturers and machine shop managers is the co-ordination of the various small interests for the purpose of sending responsible men to England, France and Belgium, and endeavor to obtain business that in the ordinary course of events would probably be overlooked by the larger interests. It is believed that many small manufactured articles will be required in the war-ridden countries, and the magnitude of these requirements in the aggregate will not be sufficient to stay the interest of those now on the trail of big business. It is the opinion of many that some co-ordinate representation, by men closely conversant with the every requirement of these countries and also the traits and desires of the people themselves, could secure sufficient trade to more than repay the initial outlay required by those firms associated in the venture.

BITUMENS FOR INSULATING CABLES

Of the few varieties of bitumen having the requisite elasticity and hardness for use as insulators for electric cables, elaterite is the best known. Since, owing to the war, this is no longer procurable in Germany, attempts have been made to prepare substitutes ("insulation tar," "insulation masses," etc.) by incorporating up to 40 per cent. or more of kaolin, chalk, etc., with natural or artificial bitumens having a dropping-point (melting-point) of about 40°-60° C. Such addition, however, only retards the flowing of the mass at higher temperatures, and cables insulated with such materials lose their shape as certainly, though not so soon, as if the unfilled bitumen were used. The improvement of ordinary bitumens, asphalts, pitches, etc., so as to raise the dropping-point, while retaining their elasticity and ductility, can only be effected by a deep-seated chemical alteration of the bitumens. For example, if the mineral matter is made to combine with the bitumen as in Schon und Co.'s patent process (not yet published), the dropping-point of a bitumen may be raised from, e.g., 41° C. to 115° C. The so-called "original Trinidad asphalt epure" has a dropping-point of about 105° to 115° C., and contains about 30 to 40 per cent. of mineral substances, but, owing to their reduced elasticity, these products cannot be used as the permanent basic material for cable masses, and are, at best, only suitable for admixture with elastic bitumens of lower dropping-point. The second method of raising the dropping-point is by chemical treatment of the bitumen without the addition of mineral matter. Only first-grade bitumens are suitable for cable masses, viz., those with the requisite elasticity, ductility, and adhesiveness, and a dropping-point of at least 75° to 95° C., whilst if the "semi-bitumens," including natural or artificial tars, asphalts, petroleum, pitch, etc., with a dropping point of 40° to 60° C. be used, the cable mass will lose its form when exposed to an external temperature of 20° to 30° C. (Dupré Chemiker-Zeitung, 1918.)

Large Offices for Railway Board.— Elaborate district offices for the Canadian Government Railways are to be established in the Great Northwestern Telegraph Building at the corner of Sparks and Metcalfe Streets, Ottawa.

WHAT OUR READERS THINK AND DO

Views and Opinions Regarding Industrial Developments, Factory Administration and Allied Topics Relating to Engineering Activity

SOLID PORTABLE VISE

By D. A. M.

THE photo shows an excellent arrangement for a vise and bench that may be wanted in different parts of the shop to use in assembling operations. The bench in this case consists of the legs and top casting formerly a part of a special machine. After the work for which the latter were built was completed the machines were scrapped, but half a dozen of the leg-and-top sets were kept for some possible future

SOLID PORTABLE VISE.

service. That service soon appeared when vises were needed for the floor hands on an erecting job. Bolted to such benches the vises were secure enough for any ordinary vise work as the benches alone weighed 200 lbs., but it was still possible to slide them along on the concrete floor to some new location. The true planed top casting made an excellent surface plate, which was of additional help to the workmen.

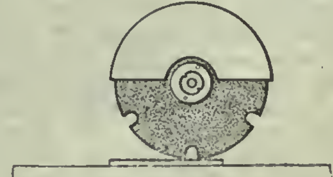
NOTCHED EMERY WHEELS

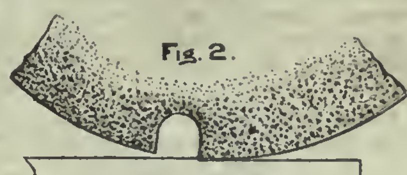
By E. N. D.

Very considerable expense and trouble was experienced by surface cracks developing upon the ground surfaces of hardened thrust washers, flat high speed steel cutters, etc., after having been surface ground.

The varying thickness of the work in question did not appear to make any difference and many schemes were adopted, including the use of wheels of different grades, varying the peripheral speed, etc., but to no purpose. As many, if not more, theories were advanced as to the probable cause, but no reason could be definitely decided upon, neither could a satisfactory method be arrived at in order to eliminate the trouble. Finally, the writer hit upon the idea of notching the wheel in six or seven places, thereby producing an emery wheel with a milling cutter's characteristics, in addition to which these notches acted the part of a fan, and immediately displaced all the small cuttings as soon as they were released, which no doubt were the cause of overheating and subsequent trouble. However, whatever the real cause was, the real cure proved to be these notches in spite of the strong opposition they met in the early stages.

Whilst the writer did not go very deeply into whys and wherefores, it may be of interest to note the following figures: With a one-eighth feed, and a cut of .009 in., there was no heat generated whatever, whilst with a one-eighth feed and a cut of .015 in there was only the slightest discoloration, imperceptible rise in temperature, and positively no surface cracks. Furthermore, there was a marked improvement in the class of grinding done, whilst the wheel did not glaze half so quickly, neither did they require dressing so frequently. Referring to the drawings, Fig. 1 shows a general arrangement, whilst Fig. 2 shows more clearly the method of notching. The idea is by no means new, but for some reason or other is not nearly so universal as it might be. The notches referred to in this article were made in a wheel 8 in. diameter, with a 1 in. face, and were made approximately ½ in. wide and ¾ in. deep. Some of the leading manufacturers prefer to have these notches made at an angle of about 45 degrees, though for all ordinary purposes a notch made approximately square with the face will be found to give very satisfactory results indeed.





FIGS. 1 AND 2—THE USE OF NOTCHED EMERY WHEELS.

AN EMERGENCY REPAIR JOB

By J. DAVIES

The shop lathe was on a rush job when burr-er-er went all the teeth off one of the feed wheels. On examination it was found that it was a 10 pitch gear with 67 teeth. By no process of mathematics known to us could we fix up the milling machine to cut this gear accurately, since we lacked the one thing necessary: an index plate with a 67 circle, or multiple of 67, as this is a prime number and could not be divided. What the milling machine hand had to say about manufacturers making gears with prime numbers would not look well in print. It was impossible to wait while we sent to the makers for a new gear, so we had to cut the gear as near as we could. This is how it was done: This machine, like most milling machines, required 40 complete revolutions of the indicator on the worm shaft to turn the gear between the centers once round, so no matter what circle is used on the index plate, or how many teeth required, the indicator must pass entirely round the chosen circle 40 times before the job is finished. From this fact the following rule is deduced: The number of holes in the chosen circle multiplied by 40 will always equal the total number of holes that the indicator passes in cutting any gear, and the total number of holes, divided by the number of teeth, will equal the number of holes for each tooth. The nearest circle that we could get on our index plate was 66, so that 66x40 = 2640 holes used altogether in doing the job. The dia. of a 6.9. The circumstance is 6.9x3.1416 = 6.3. The circumference is 6.9x3.1416 = 21.677, so that one hole would turn round the work

$$\frac{21.677}{2640} = .008.$$

to the nearest thousand. The job cannot be done absolutely correct with a 66 circle, as it would require

$$\frac{66\times40}{67} = 39\frac{27}{67}$$

holes for each tooth; by using 39 holes the error would be

$$\frac{27}{67}$$

of a hole or

$$\frac{27}{67}$$

of .008 about .003 per tooth. This would be near enough for all practical purposes if it were not for the fact that the error accumulates as we go round the wheel. This can be compensated for by going an extra hole now and again, instead of using 39 holes all the time use 40 for some divisions.

It has been shown that 39 holes leaves us about .003 short of an exact division, and that from one hole to the next moves the work round about .008 thousands, so that when our accumulated error was nearly .008 thousands we moved round an extra hole, so that by care the greatest error on any tooth was not more than .005 thousand, measured on the circumference of the gear. This was a negligible amount and could not be detected with the eye.

When forced to cut a gear by approximation like this, the actual error at any tooth may be calculated as follows:

Find out how much your job turns round by moving your indicator one hole; this will always be circumference divided by number of holes in chosen circle x40, thus

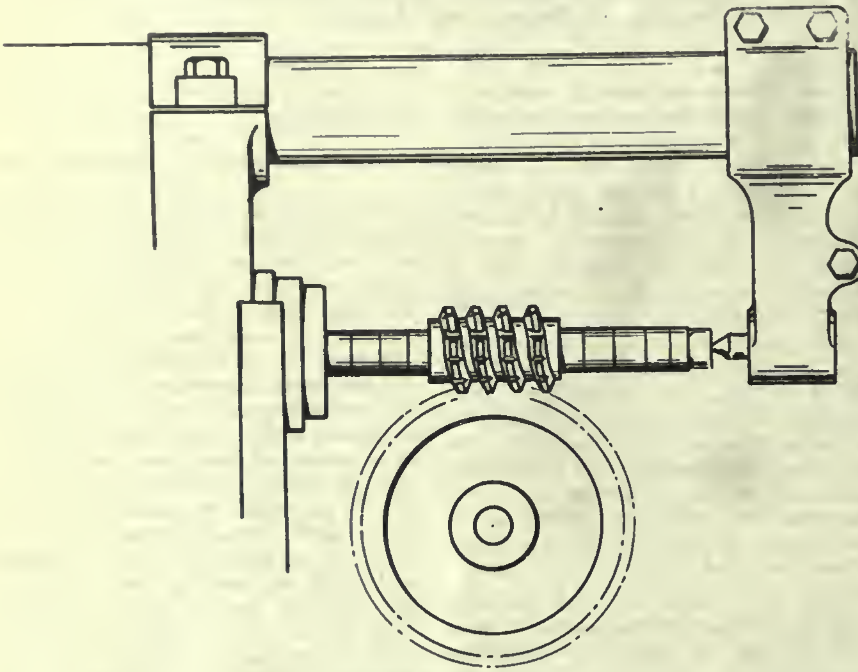
$$\frac{\text{Circumference of work}}{\text{No. of holes in circle x40}}$$

Suppose you want to find the accumulated error at any tooth, calculate the correct number of holes that should have been used according to rule given above; then count the holes actually used; then compare the difference of the two by the amount each hole represents. This will give the accumulated error at any tooth in the gear.

AN EMERGENCY HOB

By "TYKE"

A dozen bronze worm whels about 9 ins. diameter had been turned, but on account of there being no suitable hob



IMPROVED HOB

in the shop, it was arranged to send them out to be cut. A gauge was made for the worm, a dozen of which were required, and these were all finished before the worm wheels put in an appearance. When the worm wheels arrived they were duly checked and found to be shy in depth of teeth by approximately .029 ins. Had these been returned to the firm that cut them there would have been an unavoidable delay which would have disorganized the job rather more than was bargained for, the result being that it was agreed that a sufficiently good job could be made of them by hobbing them all with the worm that was to have been used with them. One of these was fluted, backed off by hand, and since it was made of machined steel, it was case-hardened very carefully, then touched up with an oil stone, and mounted on an arbor, as shown by sketch. After running one off, it was carefully checked and found to be very close to what was required, the remaining eleven being cut in exactly the same manner, and in each case they came off the miller a really first class job. In concluding, it might be stated that, due to this experience, it was a common occurrence thereafter to make up small tools, such as reamers and milling cutters of machinery steel case-hardened, providing the metal to be worked was one of the softer kind, such as brass or aluminum. For odd jobs, these very cheap tools had this advantage, when the job in question was finished, there was no serious loss in discarding them, neither was there the tendency to stock up unlimited numbers of these tools, which one so frequently sees, when they are made from cast steel or high-speed steel.

A UNIQUE LAPPING BLOCK

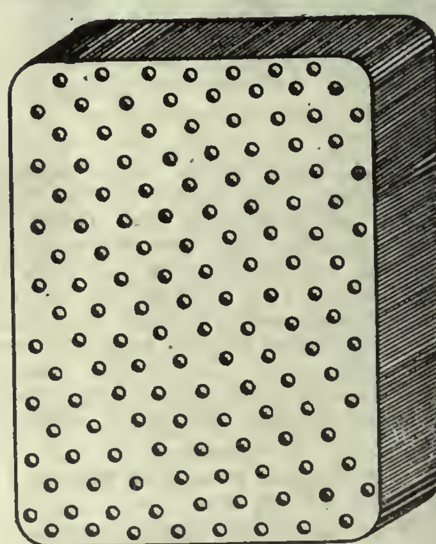
By "TYKE"

Some years ago the writer had occasion to make a small lapping block, and as the job to be done was wanted in a hurry and there being no shaping machine available, it was very necessary to utilize some other means of producing a very flat face together with the necessary cutting edges as it were. This was done by facing a piece of cast iron in the lathe in the usual way, but instead of cutting the usual chequered grooves, the block was laid out for a series of diagonal holes as shown by the accompanying sketch. These holes were drilled about half inch apart, one-quarter of an inch deep and one-eighth of an inch in diameter. The result with this emergency lapping was so very satisfactory that the holes were finally drilled completely through the block, which was kept in constant use, and in good shape by refacing from time to time.

EFFICIENT HANDLING WITH A LOW COST TRUCKING SYSTEM

By D. A. H.

There is a need in almost every plant for some sort of a shop truck between the elevating truck with its movable platforms and the common two-wheeled hand truck. In manufacturing establishments, there is a field for a truck



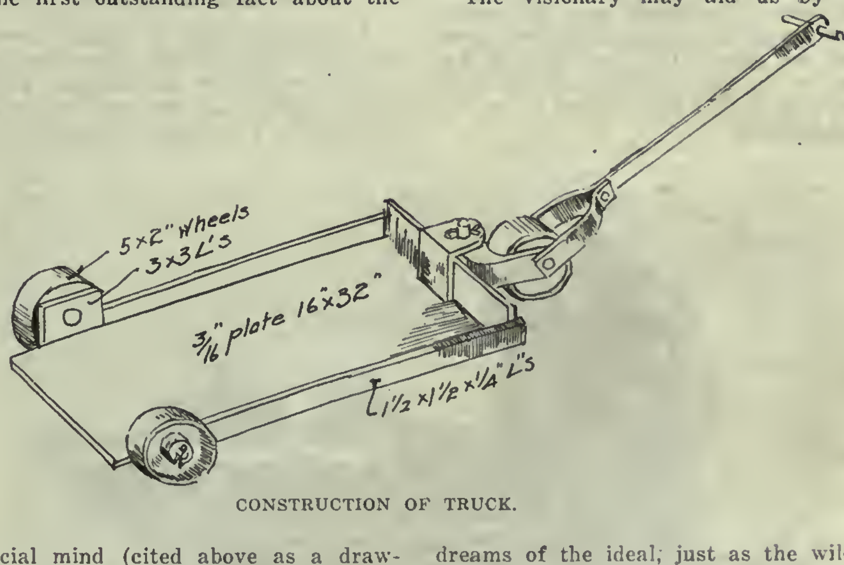
AN IMPROVED LAPPING BLOCK

to supplement the elevating truck on work carried through in smaller quantities that does not warrant or is not adapted to the latter. Often the work in one department is such that the elevating truck and platforms are too bulky for the parts produced, but some form of conveyance is needed, needed badly for the parts, either just in that one room or for inter-department haulage.

A form of truck used most successfully in one machine shop isd shown by the drawing. It is made of steel throughout with the exception of the wheels, which are cast iron. The platform is a piece of sheet steel stiffened by angles, and angles are riveted on to support the wheels. Such a construction permits a low-down platform that facilitates loading. The truck is designed for a total load of 500 lbs.

TRUCK IN USE IN THE SHOP

The class of work in this particular shop is of such a form that the parts are most easily kept in kegs or similar receptacles, and in boxes about a foot square. All of these containers are kept on the floor and the work at benches and machines is arranged so that handling the parts is most efficiently done in this way. The loaded containers weigh about 159 lbs. each, and some means of handling within the strength of the floor boy was imperative. These trucks proved to be the means. Being so low down, a box or keg could be tipped and rolled into place single handed, with no danger of spilling the contents, or need for a skilled workman to "give a hand." A total of about an hour's work a day on the part of the boy was sufficient to do all the trucking of several hundred containers in a department.



CONSTRUCTION OF TRUCK.

MECHANICAL JURISPRUDENCE

By A. L. H.

To the engineer involved in some question subject to the arbitrament of law, the facility with which the trained legal mind making a specialty of industrial cases will handle an engineering problem is surprising. Like the seaman witness questioned by a well prepared counsel, who reciting the facts preceding a collision put a definite query to receive the unexpected and surprised answer, "Why, gov'nor, you must have bin there," the engineer witness is apt to be quite as startled under cross examination. The boilermaker forean who asked in an audible voice as to "who that feller was talking to the judge" raised a smile in court by denying in an equally audible way that he was a lawyer and must be a boilermaker, and so paid a high compliment to the late Lord Alverstone.

There are many occasions upon which an engineer must exercise judicial qualities quite apart from courts of law; indeed, every man whose business is of material and human compounded must consistently exercise the faculty supposed to be peculiar to wig and gown. From the refractory customer determined to complain to the latest grievance of the casual laborer, tact and discrimination no less than more technical qualities are needed.

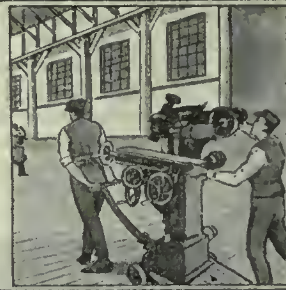
One of the drawbacks of the nicely poised judicial mind is that it sees too clearly all sides to a question, while the legal profession are notorious for the ability to produce some argument for the worst possible case.

The first outstanding fact about the judicial mind (cited above as a drawback) is essential to the engineer; without it he cannot sift evidence. The second factor above seems to be a well established shop phenomenon, for one asset of the mechanic is a good, sufficient and cast iron excuse for anything called into question by foreman or manager. The mechanical expert in a consultative capacity has to be judicial; as a matter of fact he does his best to look the part, while a late judge's definition of prevarication placed the expert witness in the lowest category.

The purchase of a new tool, of power plant, the engagement of men, the question of management itself all involve this mater of judicial faculty. It is necessary first to see the whole question, obtain all the evidence, come to a decision in face of rival claims, it is a matter of judgment; all portions of jurisprudence. The mechanical man may be less inclined to argument, may be more deductive, more intuitive; but judicial he must be, for his trade is one of the most complex in modern industrialism. When a case gets out of technical hands to the public judgment seat, it is a pretty bad case as the lawyer finds out. The inventor is rarely judicial in spirit relative to his particular project, and real criticism itself is the exercise of judicial faculty. No one will question but that the average engineer is a good critic. He is at times apt to forget that although there may be many alternatives there is usually only one course expedient. Here, however, we arrive at another question altogether, since justice and expediency are not the same. Witness the difference between law and politics, the latter purely a question as to what is expedient. There may be a sense in which the wider problems of labor, organization and vexed trade questions are matters of industrial politics, but with these for the moment we have nothing to do. It might, however, be useful to remark that just as in more general connections, justice and expediency are only nodding acquaintances. So in industrial matters it is the expedient which is practical, not the absolute.

The visionary may aid us by his dreams of the ideal, just as the wilder inventor may see where we are blind; but both neglect practical limitations and neither formulate something which can be put into terms of reality. Jurisprudence concerns itself with enactment and interpretation. exactly as the engineer must face his daily problems of complex aspect in its spirit.

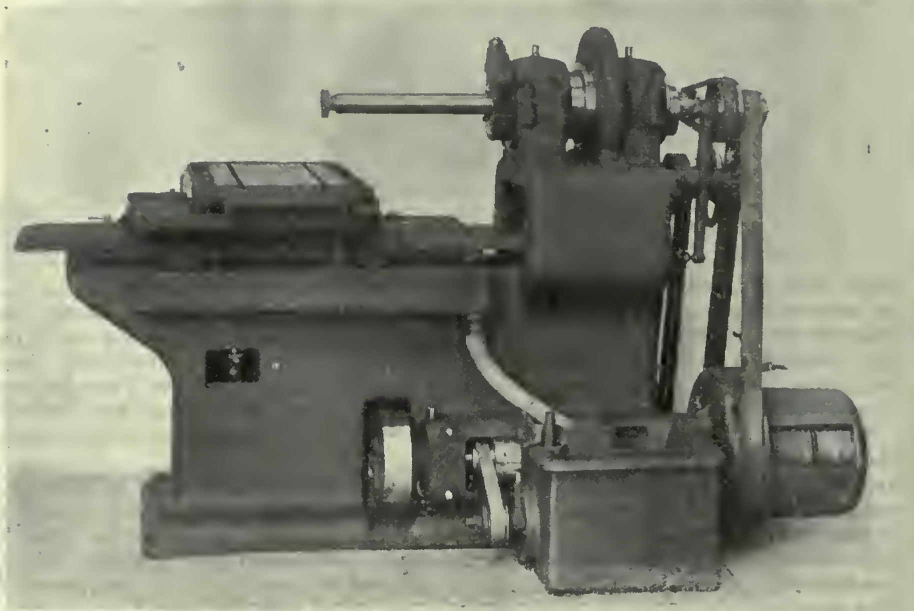
DEVELOPMENTS IN SHOP EQUIPMENT



Makers of equipment and devices for use in machine shop and metal working plants should submit descriptions and illustrations to Editorial Department for review in this section.

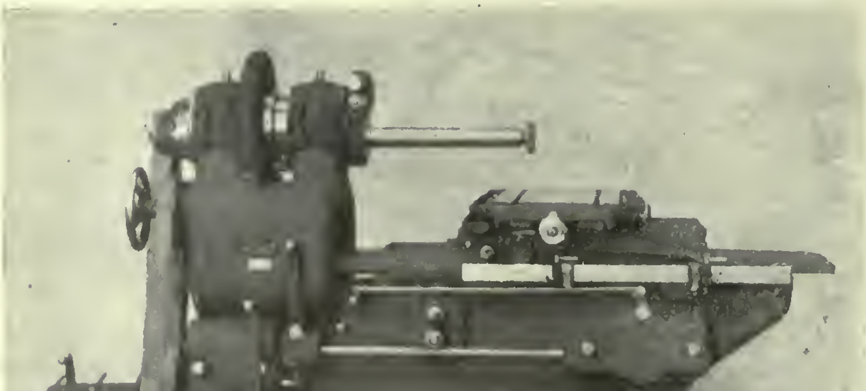
CYLINDER GRINDER

THE accompanying illustrations show a new cylinder grinder No. 65, manufactured by the Heald Machine Co., Worcester, Mass. This machine embodies a considerable number of improvements over the preceding or original machine No. 60. Instead of mounting the work table on a slide having vertical adjustment on the face of the columns, both the eccentric grinding head and work table are supported on a solid bed. This change secures a more rigid machine for supporting heavy castings, and at the same time allows as much vertical adjustment as is actually needed in general manufacturing practice. In a large majority of the plants using cylinder grinders the work table is not adjusted vertically in operating the machine, except when a very slight vertical movement is necessary for truing up a bore, which has been machined a little high or low. The work table of the new machine has a vertical adjustment of ⅛ inch to allow for whatever vertical changes may be needed when grinding castings containing more than one bore. The work-holding fixture for the new machine can be easily arranged to hold the cylinder at the required height.



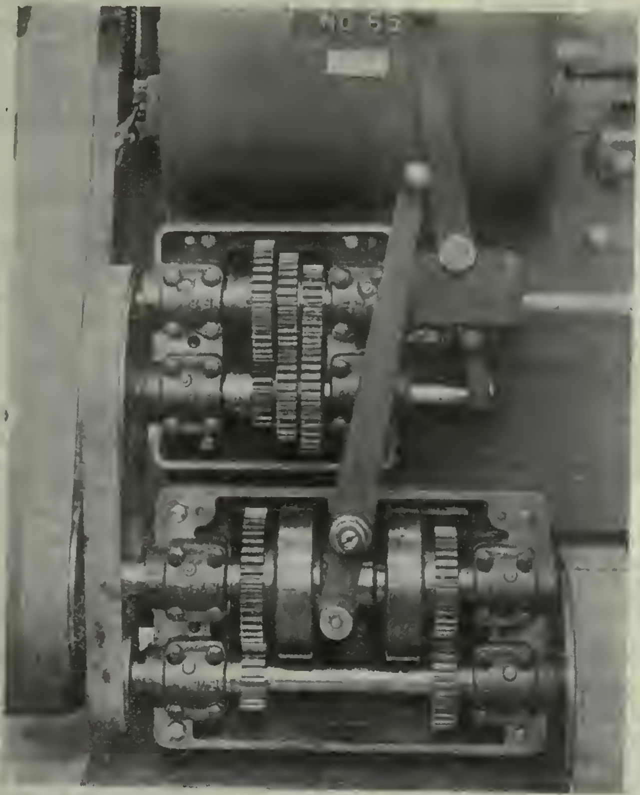
REAR VIEW OF GRINDER SHOWING WATER CIRCULATING ARRANGEMENT

An inclined slide is located between the main table and the cross feed table, which permits of the vertical adjustment. As this intermediate slide is adjustable in a direction parallel to the main slide, it moves either up or down the inclined ways on the main table, thus raising or lowering the cross slide table and the work. A hand crank turning the shaft and connected through bevel gears with a screw operates the intermediate slide.



CYLINDER GRINDER

One of the interesting features of the machine is the method of arranging or supporting the dogs, which control the travel of the table. These dogs are not attached to the main table in the usual manner, but are carried by a dog-bar, which is supported by the intermediate slide, which provides the vertical adjustment. The advantage of this construction is that the travel of the grinding wheel relative to the work is not changed by an adjustment which may be made for raising or lowering the work. The illustration showing the end view of the grinder is indicative of the excellent design of the machine. The driving mechanism there shown is another interesting feature of the machine, and differs somewhat from the arrangement used on former machines of this company's make. The main drive shaft is driven either directly from the main line shaft or from a motor, and is mounted at the rear of the machine near the base. The machine shown in the illustration is arranged for a line shaft drive—tight



GEAR BOX DETAIL

END VIEW. SHOWING DRIVING MECHANISM

and loose pulleys being provided so that a countershaft or overhead works are not required. In the case of a motor drive a single belt pulley could be employed. The grinding spindle is driven from the main driving shaft through a flexible idler, one belt connecting with the idler and another belt transmitting motion to the grinding spindle. The tension of these belts is maintained automatically by an ingenious arrangement which may be seen by referring to the end view. The tension of the belt leading from the main driving shaft is controlled by an idler, which connects with a lever which, being pivoted in the centre, carries the idler pulley upwards and maintains whatever tension is required.

The speed of the wheel spindle is changed to suit different diameters of grinding wheels by means of interchangeable pulleys, which are applied to the wheel spindle.

The gear boxes are located at the left-hand side of the machine. The lower one provides two speed changes for the eccentric head, these speed changes being controlled by a lever, which operates friction clutches of the expanding type. A cross-belt connects this speed regulating box with the main driving shaft at the rear.

A double cone of gears is contained in the upper feed box and a sliding spline provides for different rates of speed, or speed at which the work can be fed past the wheel. These changes are controlled by a lever. The automatic reversing mechanism of the machine is connected with this feed box by a shaft which extends along the front of the machine.

The main table is equipped with limit stops which automatically reverse its travel at the extreme end of the stroke, so that it is impossible for the operator to run the table rack out of mesh with the driving pinion. All the control levers for this machine are within a radius of 18 in., so that the operator may reach any one of them with the least possible effort and without stooping. The same double eccentric head which is used on the company's No. 60 machine is used to carry the grinding wheel spindle of the new machine. This eccentric head has a micrometer adjustment for readily varying the diameter of the hole being ground, and also the automatic adjustment which can be made to operate at each revolution of the eccentric head. In order to secure greater rigidity, especially for the grinding of large cylinders containing 4 or 6 boxes en bloc, the base of the machine has been widened considerably. The ways on which the main table slides are of the dovetail form, and a gib is provided on one side so that all play can be eliminated.

The lubricant pump is driven by a pulley from the main driving shaft at the rear, which also has a pulley for running the exhaust fan in case the machine has an independent exhaust system. The work table and intermediate slide are arranged to catch the lubricant, which flows to a channel or trough at the rear of the bed, and then put into the pump tank. The cover of this tank has several compartments or partitions so arranged that most of the sediment is removed before it enters the tank.

ROTARY SURFACE GRINDER

The 16-inch rotary surface grinder shown in the illustration on page 776 is the latest development of the Persons-Arter Machine Co., of Worcester, Mass.

The 16-inch size has been designed to meet the demand of manufacturers for a machine of greater capacity than the 8-inch and 12-inch models now made. These machines are admirably adapted for the rapid and accurate grinding of such work as piston rings, circular saws and knives, bearing races, valves, dies, discs and the like.

The 16-inch model is equipped with a Persons-Arter design, high powered magnetic chuck 16 inches in diameter. The machine, however, has a capacity for work up to 17½ inches in diameter and can swing work 21 inches in diameter with wet equipment and 24 inches with dry grinding equipment. The chuck on the machine can be loaded with small pieces, and within its capacity, the machine is capable of handling the same class of work as usually given to a rectangular surface grinder, thus the machine can grind rectangular work to a limit of 8 by 16 inches. The vertical capacity of the machine is 10 inches with a full diameter grinding wheel, while work of greater thickness can be ground with a small wheel.

The illustration shows the front view of the machine, the strong and rugged construction necessary to superior grinding machines being very noticeable. The massive wheel head slides in one "V" way and one flat way, thus ensuring a true movement.

Its travel can be controlled by a hand feed or automatically by dogs mounted on a rack, which can be instantaneously moved and set for any length of stroke desired, the minimum stroke being ½ inch. Minute adjustment is made by means of screw controlled pawls on these dogs.

The wheel spindle, 2 3-16 inch diameter, is made of chrome nickel heat-

ROTARY SURFACE GRINDER

treated steel and runs in large bronze bearings. These bearings are of the split tapered type, thus providing for take-up in case of wear. The spindle and its bearings are carefully protected from dust for the full length, and are easily adjusted. A solid pulley is mounted on the spindle and this, with a spring controlled idler applied to the driving belt, makes a good smooth drive and so materially helps to keep the work free from chatter marks. The belt position, it will be noticed, is set forward on the wheel slide, a distinctive feature which offsets the wheel from lifting when traversing the work.

The wheel slide is automatically controlled by a single tension spring reversing mechanism. On the shaft, on which the three step cone pulley seen is mounted, are two small bevel pinion clutch gears which are constantly in mesh with a large bevel gear. This bevel gear is mounted on a shaft which drives the slide through a pinion gear, vertical shaft and rack. These pinion gears run free on the shaft until a double-faced clutch, slidably keyed on the shaft, engages the clutch teeth on the inner face of either pinion gear according to the direction the slide is to travel. The clutch is shifted by a lever which is actuated by adjustable dogs on the wheel slide rack. To the lever are attached two legs connected by a tension spring of sufficient strength to shift the clutch into mesh with either pinion gear instantaneously.

The slide for the raising and lowering of the work-table runs in broad bearings, and is raised or lowered by a hand wheel bearing on indicator disc, graduated to half-thousandths of an inch. A tapered adjusting gib runs the full length of the slide and it can be raised or lowered by turning a screw at the top, thus changing the adjustment equally at all points of the slide.

The chuck or work-table spindle has a hardened steel collar with a tapered face shrunk on it at the upper end.

The spindle is driven by a large bronze worm gear mounted on the end of a universal shaft. This gear is constantly in mesh with a large cast iron gear running free on the spindle and which can be locked and made to rotate the spindle by means of a friction clutch. The entire chuck spindle bracket is pivoted on a taper pin so that it can be titled forward or back for grinding bevelled or dished surfaces. The bracket is adjusted by means of a screw showing just above the plate which indicates the angle of adjustment.

The magnetic chucks used are radically different from most types. The chuck proper is composed of but three castings, the body, core and bottom plate. These parts are all made of the very best grade of electric furnace steel obtainable and have a permeability equal to that of the best Swedish and Lancashire iron, which means that they will carry a maximum of magnetic lines of force per square inch.

The chuck face is so designed as to give the greatest amount of magnetic edge, which necessarily ensures tremendous holding power all over the face and pieces as small as ½" in diameter can be held at any place on the face. A single, high power, circular coil is used, and the current is specially calculated so as to produce no excessive heating.

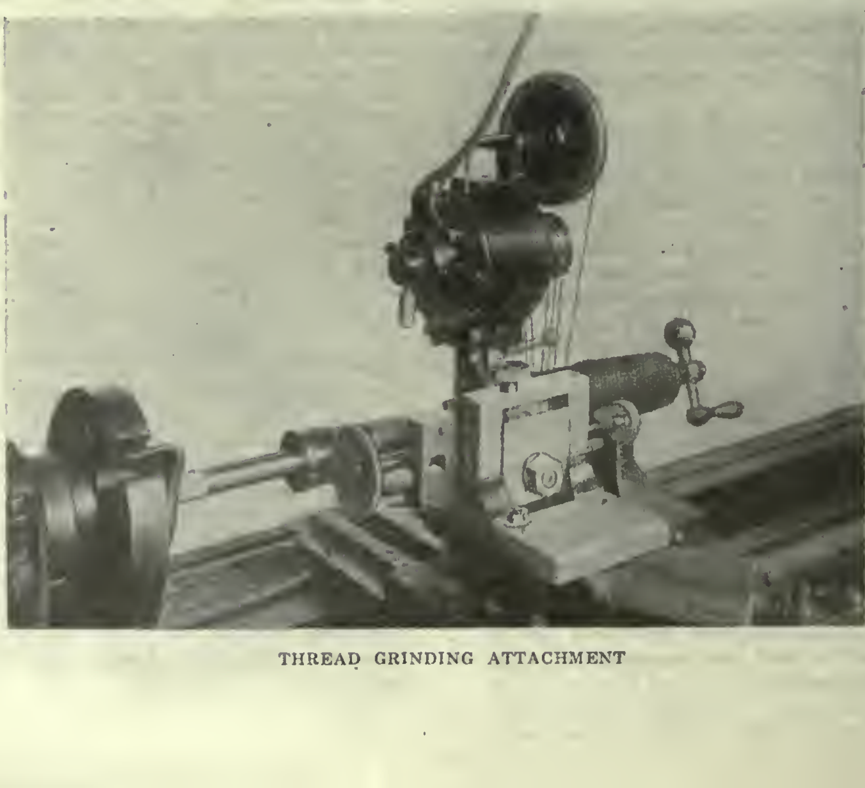
A demagnetizing switch is supplied so that work can be removed from the chuck by simply throwing back the switch, which reverses the current for an instant and so demagnetizes the chuck.

THREAD GRINDING ATTACHMENT FOR LATHE USE

The excessive demand for master thread gauges for the rapid and accurate manufacture of munitions has clearly proven the uncertainty and the impracticability of the lapping method of their manufacture. It has furthermore demonstrated the desirability of a more rapid method of manufacture. The International thread grinder, made by the International Equipment Co., is the result of three years' experimenting in connection with thread gauge work and promises to be of high value in the manufacturing industries of peace as well as of war. It will do practically all that a large and expensive cylindrical grinder will do and other operations beyond their scope are easily possible.

The grinder may be attached to a lathe compound rest as easily as any other tool. It has an individual motor drive through a continuous round belt which permits of the greatest flexibility. Vibration from the lathe cannot be transmitted to the wheel. The spindle is mounted on Norma dust-proof ballings.

The wheel can be run up to 7,000 revs. per min. and is trued with a diamond which can be set accurately and quickly to any desired angle. This device insures the exact shaping of the wheel to the form of whatever thread is to be ground. It is easily portable, weighing only 50 pounds. and occupies very little space. Standard cylindrical gauges, both plug and template, are ground to size after hardening without the necessity of lapping. Reamers may be ground, taper and straight and may be backed off.



THREAD GRINDING ATTACHMENT

THE EXPERIENCE OF NINE YEARS BUILDING TRACTORS IN CANADA

The Mistake Was Made in the Early History of the Enterprise of Turning Out a Machine Too Heavy For Practical Use on the Land

By JOHN MUIR, President Goold, Shapley & Muir Co., Ltd., Brantford

"OUR Company have been manufacturing tractors for nine years. We started with 28 HP. machine, belt power; weight 12,000 lbs.; this engine would pull three to four 14" plows.

"At a trial held under the Winnipeg Industrial Exhibition about this time, the American manufacturer had larger and heavier engines of sufficient power and weight to pull six and seven 14" plows. The Western farmer paid but little attention to what was then termed by them our little tractor, and followed the larger machine. This condition inspired our Western branch houses with the idea that there should be engines of larger capacity, and they prevailed upon us to produce a larger engine. At the next trial, a year following, at the same exhibition, our company exhibited a 35 HP. engine, belt power; weight 14,000 lbs., which had the power to pull five 14" plows, but the American manufacturers had again produced larger than their former engines and exhibited engines that would pull ten and twelve plows, and we were then prevailed upon to build a still larger engine, and the third year at the Winnipeg Exhibition, we exhibited a 50 HP. engine which weighed 17,000 lbs.; some other makes of the same power weighed 23,000 lbs.

"This condition has by actual experience in the traction engine business, namely the production of heavy engines of larger power, been a most unfortunate chapter in the development of the tractor business to the Western farmer, and many of these farmers were placed in a very awkward position financially through having to pay for these heavy engines which were unsuited to the work which they had to do with them, and while this is true, the loss was also very heavy to the manufacturers, who were compelled to take their engines back in many cases and they were largely scrap, and very often handed back the money or notes to the farmers who had purchased, rather than injure their reputation.

"The Hon. Mr. Motherwell, Minister of Agriculture for Saskatchewan, wrote letters in the Agricultural papers in Western Canada, condemning these heavy tractors, and warning farmers against using them, and this seems to have been the end of the heavier traction engines for agricultural purposes. Following this, there has been a race as to who could produce the smallest and lightest tractor. I have a report in an American paper, namely, 'Farm Machinery, Farm Power,' published in St. Louis, Mo., before me, giving the names of six men killed and four injured for life, by one of the lightest made tractors toppling over backwards on the operators and crushing their life out. This is an engine of an American make.

"In reference to present day and future tractor business, there is undoubtedly a good business to be done in this country and, in my judgment, it will continue to grow, if the proper tractor, namely, a tractor of the right size and weight, is placed in the farmers' hands. What is needed is one that is adapted to do the work required of it, both in the field and by operating from the belt, and there are thousands which will be required.

"Conditions, however, for the use of a tractor, should be considered by the farmer before he purchases. On rough, stony farms the farmer would be well advised to use horses and not tractors for the tilling of his soil.

"From my observation, my judgment is that two sizes of traction engines are required to meet the different conditions and work where conditions vary as to the requirements. The ordinary farmer should have power enough in the engine he purchases to fill his silo in a hurry, run a medium-sized thresher, grind his grain, and take care of all power requirements on the farm, and also to pull three or four plows, according to the condition of his soil, and if desired to draw the other implements to till the soil and take off his harvest. There may also be a limited place for a smaller tractor in some cases. I have given you, shortly, my views and the experience of our company in the tractor business to date, and I trust it may be of interest to your readers."

Trade Gossip

Alteration to Plant.—The Chatham Packing Co. has applied for a permit to remodel their plant on Whitehall street at a cost of $12,000.

Province to Build Hospitals.—The Public Works Department of the Province of Alberta are planning the erection of hospitals at a number of small towns through the province.

Engineering Contracts in Toronto.—The Roman Catholic School Commissioners will call for tenders in connection with the heating, ventilation and plumbing for the new St. Patrick's school now being erected.

To Locate in Vancouver.—It is stated that the Sydney Rubber Co., Sydney, B.C., will erect a manufacturing plant in Vancouver in the near future. The manager is Mr. B. D. White, 402 Pender street west.

Regina Wants New Branch Lines.—A resolution was passed recently at the meeting of the Regina Board of Trade asking the Dominion Government to construct a branch line connecting Regina with Avonlea on the Canadian Northern Railway.

Large Building Programme. — The Government of Alberta are considering extensive building plans for 1919 and 1920. These include a new government building on the capital grounds. The provincial architect has received instructions to prepare sketch plans for the first unit of a large number of departmental buildings, which will eventually be constructed on the ground to the south of the capital building. The Department of Agriculture will ask for an appropriation for a number of buildings to be erected during the coming year. It is proposed to build a dormitory at each of the farhing schools in Vermilion, Olds and Claresholm, to cost about $150,000 each.

Unfilled Steel Orders.—The United Steel Co. of Canada had on hand at November 30 unfilled orders to the amount of 8,124,663 tons according to the corporation's monthly statement. This is a decrease of 228,630 tons, compared with the orders on October 31.

War Trade Board Announcement.—"In view of recent developments which have made the steel situation somewhat easier, and especially in view of the fact that certain United States restrictions have been lifted and others modified, permitting shipments of plates, boiler tubes, etc., being made to Canada more easily than in the past, in future it will be unnecessary to apply to the War Trade Board for releases from stocks on forms which were provided for this purpose, neither will it be necessary to supply monthly reports, as in the past. Dealers and others are now at liberty to dispose of their stocks wherever they can, but the War Trade Board reserves the right to fix the price of the same in the event receiving complaints to the effect that prices which are being charged are excessive."

Looking For Trouble

THERE are a number of people in Canada at the present time who are going to be greatly disappointed if this country is not going to have its fair share and a little more of dull times.

Of course, they are not going to get up openly and state that this is their avowed policy, but they are doing it in another way, one which is quite as effective as though they climbed on the house-tops and shouted from the roofs.

The first thing they start when meeting a friend in casual conversation is something to the effect that we are in for some dull months—a lot of people out of work—the manufacturers not going ahead with any new lines—thousands of soldiers coming back with nothing to do—you know the run of their talk. It's generally done in a whisper, in a doorway, not very often out in the open, where some red-blooded citizen could get hold of the thing and put it out of misery.

The Ottawa representative of *Financial Post* puts the case well this week when he says:

> "All over Canada the suggestion of coming trade depression seems to have gained considerable currency. Men are, commonly, pessimists, and like to prepare themselves for the worst when there is no particular reason why the worst should happen. If they confined this feeling to themselves the trouble would be, as the doctors say, 'localized'; but your true pessimist delights to go about infecting his neighbor with the germ. 'The awful slump after the war' is an expression which has got into the mouths of too many people who are otherwise sensible. Such people show just about as much good judgment as the proprietor of Amerongen Castle who invited that other awful infliction, the ex-Kaiser, to come and visit him."

One might almost surmise that some of these blue-ruin shouters would have wished that the war and the killing at the front could have continued indefinitely in order that business might remain extra good for their particular line. The fact that the casualty list of our men has ceased to haunt us daily weighs with them not at all.

If these whisperers of dull times would only expend half the energy in preaching hope, optimism and courage as they are in aiding a cold feet campaign, they would indeed do a service well worthy of the name.

A Commercialized Christmas

THE mad campaign of forced selling, the constant striving to create an unnatural feeling of excitement, are doing much to make the Christmas season a nightmare instead of a blessing, a time to be dreaded rather than joyfully anticipated.

The big stores have grabbed Christmas. They have annexed Santa Claus, and they have turned the whole outfit into a dizzy whirligig, not to spread or create joy, but simply to separate the people from more money than they would spend were they left to their own common sense and the limitations of their purse.

The real spirit of Christmas has been backed so far into the ditch by the gorgeous procession of a commercialized season of festivity that it hasn't got one chance in ten to get a hearing.

There is calm deliberation that spoils anything approaching spontaneous giving.

In too many cases we give in 1918 because we received from the same source in 1917. It is a mild form of bargaining, and it grows and increases until many a person finds himself approaching Christmas with a feeling closely akin to a mild form of financial hysteria.

The simple little gift, prompted by affection, given with no thought or expectation of a return present, is the nearest approach to the real Christmas feeling. It is getting squeezed so hard by the commercialized Christmas that the chances seem to be that it will pass out and give up the struggle.

What the world needs and longs for is a sane, sensible, real Christmas—one that reflects the meaning of the season, and refuses to become partner to the annual scramble to fling money into the coffers of merchants who must unload their truck or cut the price.

The Hat With Ear-Tabs On

WHEN the wind turns to the north, me boy, and blows to beat the band, as though it was a-comin' from some icy, snow-bound land; when it sifts in past the cellar door and through the keyhole, too, and makes the knuckles on yer fists turn sixteen shades of blue—when the cistern pipes get all friz up and the bloomin' thing won't spout, until you get the kettle and begin to thaw her out.

Oh, it's then we feel our ears get cold as they flop out in the breeze, and sway before each bitin' blast like some old poplar trees—our old felt hats and hard ones, too, they cover up our dome, but they leave our ears a-stickin' out to face the frost and foam.

And yet you see folks goin' around wrapped up in furs and rugs, but not a thing about 'em for to bolster up their lugs—they hold their fists up to their ears, they wheeze, they blow and cough as though they was a-goin' to shake their thinkin' tank right off.

I ain't got sympathy for them what prowls around like that, determined in the zero days, to wear a summer hat.

Ah, let 'em go to some old trunk where boyhood stuff is stored, and where the olden garments live for times when winter roared, and let 'em cast away their pride, they know right well. I swan, they'll get again that fuzzy cap that had the ear-tabs on.—ARK.

Canadian newspaper publishers pay about $3,500,000 a year for their white paper.

Some of the largest Canadian and American newspapers consume from 50 to 100 tons of paper daily.

The daily consumption of newsprint paper in Canada is, approximately, 250 tons; in the United States, 5,750 tons.

Canada's daily output of paper, made into a continuous strip three feet wide, would be long enough to girdle the globe at the equator.

There's Big Business Ahead of Canada

CANADA is glad that the war is over.

War business was good. But back of it all there was a feeling in the heart of every man worthy of the name that there was something undesirable about the business. It meant employment—it meant dollars—it meant big money—it also meant death, mutilation, suffering and heartbreaks.

Industrial Canada longed for the day when the word "war-trade" should be removed. It meant less business, some disorganization, some loss. But away and above that it meant the removal of that nightmare that had haunted Canadian firesides for endless months—the casualty list.

So when you are minded to mourn the loss of war orders, put the two things in the scales, stand back and look at them. There they tilt, dollars on one end of the beam, lots of them—on the other our own men and boys, our sons, brothers, fathers and friends. It doesn't take long to decide, does it? We gladly reach out the hand, and, brushing the dollars aside, welcome back the civilian soldiers to our midst.

Canada's war achievement in the turning out of shells, fuses, airplanes, ships, and all manner of munitions and supplies, has been remarkable.

When Canada turned to shells the impression seemed to be that a few tinkers had gone crazy.

The number of people who accepted it as a fact that Canada could solve the problem, reach capacity production and keep the product to the high standard necessary, were few and scattered.

The pioneers soon proved that it could be done. The circle of shell plants widened, and it became an accepted fact that the Canadian shell shop was a great, big, strong link in the Allied chain that was going to put an end to Kaiserism.

And now for the future?

Don't make the serious error of thinking that recovery is the work of a day or a month.

Along with the rest of the world, Canada has been war-sick. The doctors in charge, Foch, Haig, etc., have announced that the patient is going to recover. Canada is recovering, and her tremendous resources, her financial position, her broad acres, her powers of construction, and the initiative and determination of her own people will work wonders.

There is, perhaps, a tendency to hold back in some cases, to see what is going to happen, to watch what the other fellow intends to develop. When you find a lot of men holding back it's an easy matter for one courageous chap to step out and take a lead that it's mighty hard to take away from him afterward.

If you've made money during the war period, remember that it was from an abnormal cause. Remember that your money was made while others were getting shot and shot at. Remember that there is a responsibility on your shoulders that you dare not discount, and a burden for your back that you dare not shift.

There is big business on ahead. And it is for him who prepares for it. This preparation calls for study, for investment, for patience. You owe it to the man who shouldered a gun and went away to fight your battles to see to it that he has a decent place to live in when he comes back. Don't let him return to the place that urged or forced his enlistment, and cheered his departure, only to find that it's a barren and a jobless land.

Be as liberal and brave with your dollars as you expected him to be with his life and limb.

Canada is a great country—a wonderful place. It needs sane and careful development. It needs to be turned into a good place for the man who wants to do an honest day's work and into a mighty poor place for the man who wants to loaf or camp on the necks of his fellows.

There's a big gap between the farming interests and those of the manufacturers. There are men abroad, who for purposes of political expediency, are making it their business to dig trenches and build barriers between these two great interests. They do not want the farmers to understand or appreciate the problem of the manufacturer, nor do they desire the manufacturer to be in a position to become familiar with the business side of farming.

The longer the farmers and manufacturers fight each other, the better pleased will be the political pirate.

There is room in Canada for farmers and manufacturers. They are both here now and they are going to be here in large numbers in years to come. Their best interests are going to be served by a mutual understanding and a cessation of small squabbling for political purposes.

Canada is going ahead. Canada is not going to the bow-wows. Make that your starting point. If you've got any doubt on your mental slate, reach over and dip your rag into the big pond of optimism and get that slate right.

Get your eye on the big business of the future. It's there just as sure as Tuesday follows close on the heels of Monday. But it's for the man who is brave enough to go out and get it. There's not much brought in these days to the doorstep of the man who shivers at problems that to bigger men look like golden opportunities.

PREMIER TROOPSHIP ARRIVES AT HALIFAX

THE photo shows the giant White Star liner Olympic on her arrival at Halifax last Saturday with nearly 6,000 Canadian soldiers on board. The trip marked the completion of her 19th voyage from British ports to Halifax, and she brought the largest number of returning soldiers that has yet been carried to any Atlantic port. The Olympic, which is the queen of the White Star fleet, was given a rousing welcome. For nearly three years this grey leviathan has come and gone without ever a line about her movements being printed. Week after week, under the skilful command of Captain Hayes, R.N.R., D.S.O., she ran the gauntlet of the German "U" boats with her precious cargoes of fighting men. Of the 70,000 Canadian soldiers she carried from Canada to the Motherland, not one was lost at sea. Note the manner in which the big liner is camouflaged.

THE record made by Canadian shops in the production of munitions can hardly be appreciated by the people of Canada. In years past we have been in the habit of taking it for granted that our industrial efforts would be of secondary importance. We have hardly dared come to the conclusion that as a producing people in an unknown line we could lead the procession.

When it was first proposed that Canada should undertake the production of munitions the manufacturers were inclined to be skeptical. It was something new—the war might end at any time—a lot of new and special purpose machinery was required. In fact it was some time before the more energetic manufacturers had come to the stage where they found that they could make munitions, and make them successfully.

In fact, Canada's effort in munitions was in keeping with the record made at the front by her sons. The number of decorations won on the field of battle tells the story. The figures are complete only up to July 1st, 1918, and the totals would be increased considerably.

NORWEGIAN CONTROL OF THE MOLYBDENUM MARKET

The growing importance of molybdenum in the manufacture of steel is giving Norway an influential position with regard to that industry. Numerous discoveries of molybdenum ores have recently been made in that country, and its Government has taken steps to secure to native industry the advantage of this discovery.

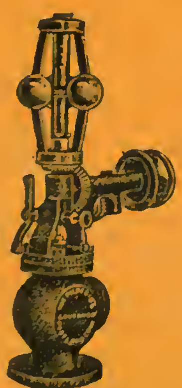
PICKERING GOVERNORS

EQUIPPED WITH BALL SPEED RANGER

MANUFACTURED BY THE

PICKERING GOVERNOR CO.

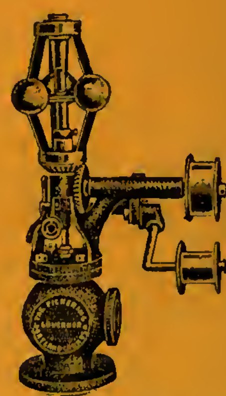
Portland, Conn., U.S.A.



Class B style.
Includes Speeder and Sawyer's Lever.

We are also prepared to combine the Stop Valve in Governor body without any service complications. Either Class B or Class A style of upper works can be fitted to this **combined Valve Chamber.**

This Governor is very popular throughout the Dominion, brought about by constant efficiency, reliability and durability.



Class A style.
Has all Class B features and also Automatic Safety Stop.

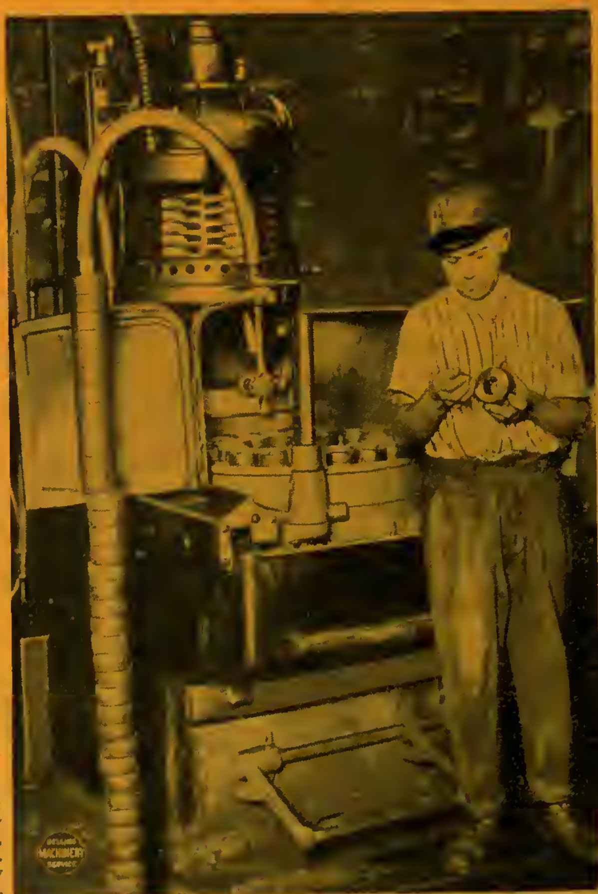
Blanchardize Your Machine Parts

Excellent Results at the Hendey Plant



This collection of parts is finished on two Blanchard Grinders, the first installed 6 years ago, the second one three years later, in the Hendey Machine Company's plant, at Torrington, Conn., and is an excellent example of the economy of "Blanchardizing." There are lathe aprons—ground on two surfaces and subjected to an unusually rigid inspection test—gear housings, outside gear boxes, vise jaws, gear box covers, collars and a dozen other parts, besides blanks for all of the twenty-one gears used in the Hendey Lathe—ranging in size from 1¾ to 9 inches diameter and ground to limits plus or minus 0.0005". Versatility is not the only feature to recommend "Blanchardizing," but it is important. Speed and accuracy are additional advantages. Let us tell you more about these machines.

G & E Automatic Gear Generating Machines

Gould & Eberhardt Gear Generators are specially noted for symmetrical work in spur, helical and worm gear cutting. These machines possess many special features that contribute to a wider range of cutting and greater economy than ordinary hobbers. Ten changes of speed—all hardened steel driving gears—rigid work arbor support—single pulley drive—and rigid cutter slide are a few of the many special features of these productive hobbers.

Complete description in Bulletin.

Saving in Transmission Saves Coal

Tests under working conditions have shown that the American Steel Split Pulley will transmit more power with less waste than any other pulley on the market.

These tests can be verified by or repeated for any responsible engineer who wants the truth about pulleys, or we will, upon application, forward detailed printed reports.

AMERICAN STEEL SPLIT PULLEYS

Guaranteed for minimum belt slip, minimum air resistance, double belt service.

Correctly designed for maximum strength and light weight and guaranteed as to material and workmanship. National distribution through supply houses.

Write to-day for "Getting Maximum Pulley Efficiency"—a 37-page booklet which tells how to eliminate unnecessary pulley waste.

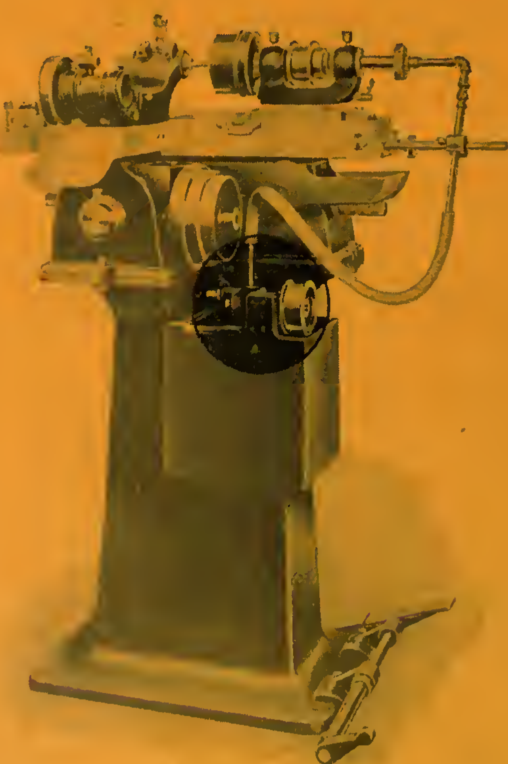
TRAHERN

Rotary Geared Pumps

The Utmost in Efficiency and Durability

Trahern Positive-drive Rotary-geared Pumps shoot the lubricant into deep bores or other work difficult to cool. Never need to lessen the speed of the cutting tools for the reason that Trahern Pumps, even at slow speed, flood the cutting tool with abundant coolant.

Moreover, you can positively depend on Trahern Rotary Geared Pumps to maintain a full, continuous stream of the coolant **without** friction-making sediment, **without** pulsations and **without** clogging.



We positively guarantee that Trahern Rotary Geared Pumps deliver all the coolant possible to force through the discharge opening while operating at a speed of only 300 to 500 R.P.M. It's little wonder their service life is almost as long again as that of centrifugal pumps, which, to deliver an equal volume of lubricant, must bear the wear and tear of a speed twice as great.

Let us send a sample pump free of charge—to prove that Trahern Geared Pumps are preferable.

TRAHERN PUMP CO., ROCKFORD, ILL.

MARKET DEVELOPMENTS

Signing of Armistice Changed Many Prices

Markets in Some Cases Have Had a Wild and Merry Career During 1918—Machine Tool Dealers Moving Very Carefully With Regard to Taking on Used Shell Shop Stuff

ONE of the most outstanding events of the year has been the very high price at which ingot tin sold. The quotations referred to here are New York figures, and to them should be added duty, freight and exchange. At the first of the year tin was quoted at 80c lb., while on January 10 the price had gone to 85c. From January 16 to the end of February there were practically no quotations at all as no tin was available. On May 2 tin had reached $1, and by May 13 it had touched $1.05. The price remained practically at that until the end of October. Last quotations were at 70c. The high value at which tin traded doubtless made fortunes for some of the speculators. In fact it was a highly fictitious price all through, and did not represent the intrinsic value of the metal. There was a great falling off in consumption by the usual users of tin as the governments in several countries made it impossible for makers of tin cans, etc., to enter the ingot market for their supplies. In the usual course of events this country anticipates a certain amount of tin from Dutch West Indies, but the Dutch Government secured control of it and prevented export. Supplies from Malay Straits and the Grecian Archipelago did not arrive. The situation was controlled almost directly by the British Government. Munitions used very small quantities of tin, and although the price was very high the demand for it was not as keen as though the extra work being done called for larger proportions of tin.

Copper has had a rather uneventful year, although there has been a very great deal of it produced and used, the demand being largely augmented by the calls of munitions plants. The January price was 23½c, which was raised by the War Board of United States in July to 26c, at which price it will remain until the end of the year. Casting copper was uncontrolled, and the strange part of the situation is that this sold at a higher figure than lake and electrolytic, an event not experienced before as it is an inferior article.

There were no outstanding surprises during the year in spelter or lead. Spelter was fairly strong around the opening of the year, but declined, at present being quoted at 7¾c. There was a fairly active trade in lead.

The Scrap Metals

The scrap metal market has followed a peculiar course during the year, but one very closely connected with the trend of war trade. At the outset it should be remembered that copper constituted the great bulk of the trade as far as the open market was concerned, as the steel turnings from shell shops were directed and controlled by the Imperial Munitions Board. The trade has been under fairly close supervision from the War Trade Board at Ottawa for some time past, and it has been necessary to report the amount of material in yards, the amount received, and the amount sold. The export of scrap to the States has been under embargo with the exception of copper and a number of grades of brass. The market has been dearer here than in the United States, and for that reason there was not much advantage in looking to the U. S. market as an outlet for Canadian scrap.

The labor situation has not helped matters much. In the months when the yards were pressed for help it was almost impossible to secure the required hands for sorting material. There is a marked change now, and an unfortunate one. Men are looking for work and the yards are in a state of complete inaction.

Dealers are not in the market now. That statement can be accepted as quite truly representing the real state of affairs. The bottom has dropped out of the market, and there does not seem to be any immediate prospect of any person being able to put it back in. Sellers having offerings that look good are being advised if they can do so to hold on to them until the market begins to take on a more definite form. Even where quotations have lowered on shipments no improvement is noticed. Figures that are given as representing the value of offerings are no true indication of the real state of affairs. For the purposes of actual trading just now one might just as well begin on the assumption that there is no price list at all.

The Selling of Steel

There are two outstanding features in the steel market for the last year or so. One is the very high price to which some of the lines moved, and the other was the way in which the steel interests stood behind the Government when their industries were brought under control. It is a matter of record that steel plate was sold in Canada as high as 17c per pound during the war period, and a high mark of 12 cents has been established in some cases this year. The matter of price regulation was taken up at Ottawa, following the formation of the War Trade Board, and from this was worked out the rather intricate and sometimes confusing system of licenses, priorities and permits, etc. There was very little effort to put anything over the Government on the part of the mills or dealers. There was a good display of practical co-operation and this feeling was of tremendous benefit to the government.

One of the first lines to feel the price control regulations was that of ship plate. The Government decided that they would recognize a maximum price of 10c from the warehouses and 7½c at the mill where the material was rolled. As soon as the armistice was signed this price began to slip and to-day's quotation is 7c from the warehouse.

It has been a hard matter for the trade to keep in stock anything approaching a complete assortment of boiler tubes. The mills were not allowed to take skelp for the making of tubes, and on that account there was a shortage that interfered even with the most necessary repairs.

Toward the end of the year there has been a pronounced shortage in sheets, with prices at high levels. In common with other lines this situation is being relieved and the price is subsiding.

Machine Tool Selling

One of the outstanding features in

EVENLY MATCHED

The man who is tapping internal screw threads with a Geometric Collapsing Tap is evenly matched with the one who is cutting external screw threads with a Geometric Self-opening Die Head.

Commenting on the policy of THREADS, the monthly publication of The Geometric Tool Company, a London supporter of the Geometric method says:

"The policy you advocate as to work is good, yet you are inconsistent in making a tool that avoids it."

Geometric Self-Opening Die Heads and Collapsing Taps

Help You to Avoid Work by Doing It for You

The Geometric Catalogue will tell you how.

THE GEOMETRIC TOOL COMPANY

NEW HAVEN CONNECTICUT

Canadian Agents: Williams & Wilson, Limited, Montreal; The A. R. Williams Machinery Co., Limited, Toronto, Winnipeg and St. John, N.B.

connection with the trade of the year, and with the trade of the entire war period for that matter, is the fact that nearly the same machine tool dealers are in business now that were when the war began. There has been a very large volume of business handled. There have been plant lay-outs made that are a credit to the skill of Canadian mechanics and salesmen. There has been a searching from coast to coast for machine shop capacity to turn out machinery for the production of shells. The work of keeping all these sub-contracts in line and also keeping them working at the same pace was indeed a problem to puzzle the most experienced.

There is a large amount of machinery offering now from the shell shops. A good many sales would be made were the dealers willing to take in the shell shop stuff on the basis of part payment on new material. It is not likely that this will be done to any great extent, although there are times where a machine is good and has been well used or perhaps used very little at all. The straight single-purpose machine will be scrap and there is no help for it. Other machines that were adaptations from standard machines with shell equipment may be altered and changed for their original work. Then there is a great deal of general-purpose machinery that is capable of being turned to many other lines. Some fairly large-sized deals have already gone through whereby dealers have taken over parts of this material. When a dealer finds a plant that has used machinery that has been well cared for, or that has not been in operation for a great length of time, he has a chance to store and hold this for future sale. Other firms are refusing to consider used machinery at all, either on the basis of a deal or a sale.

MONTREAL REPORTS THAT SALES ARE MADE IN USED MACHINERY

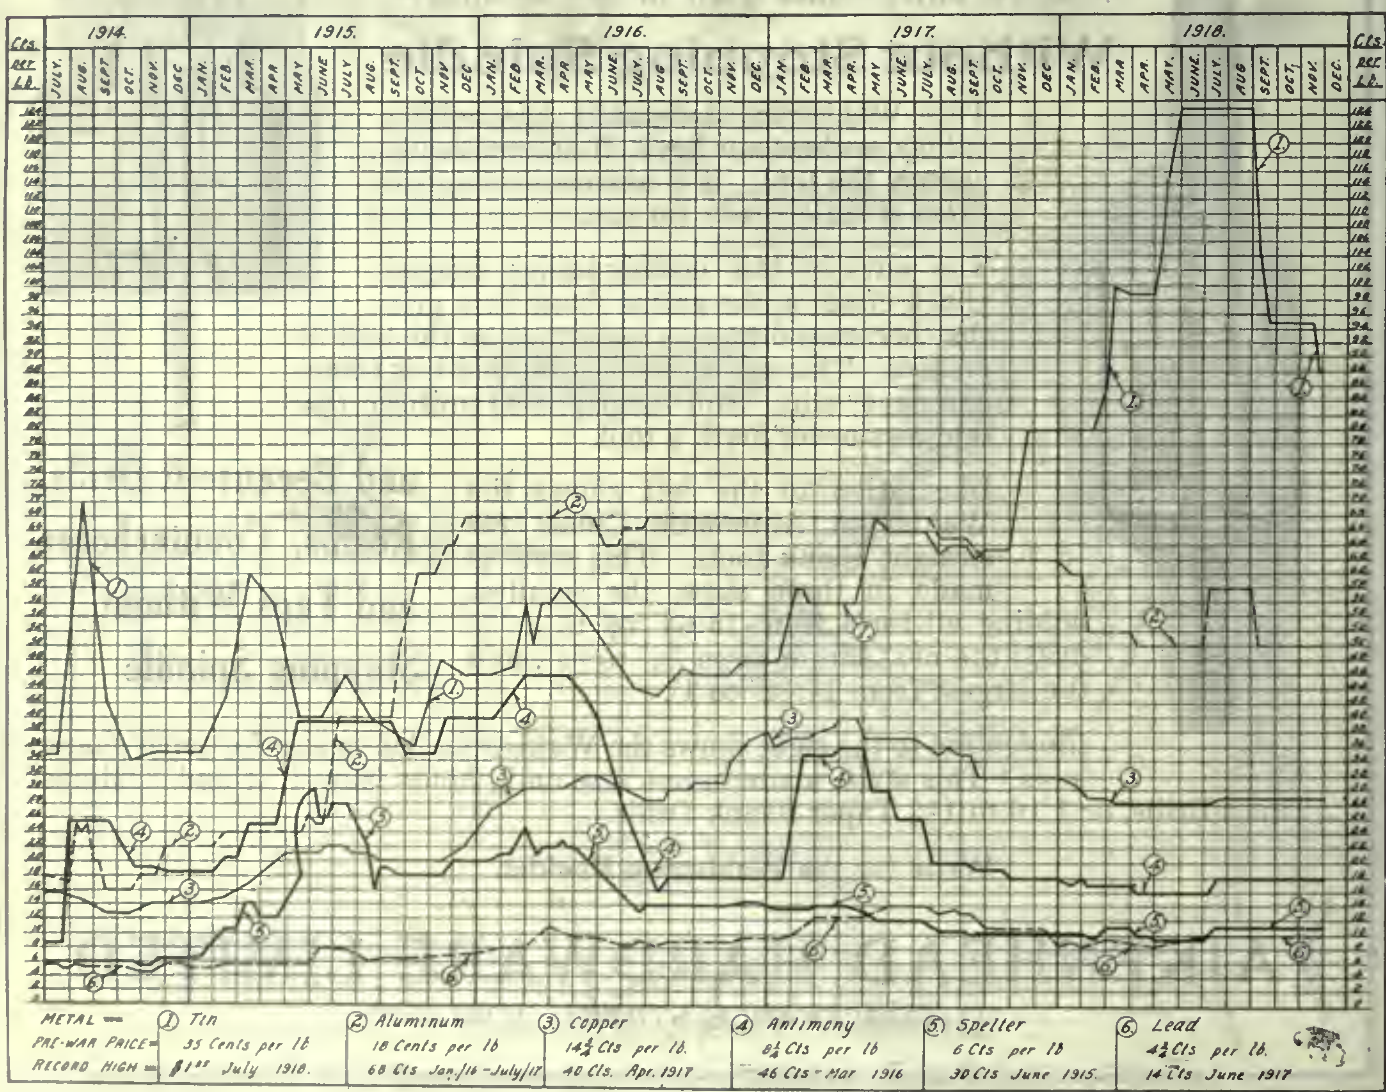
Special to CANADIAN MACHINERY

MONTREAL, December 26, 1918.—Despite the falling off in industrial enterprise as a result of cessation of war activities, business is proceeding as usual, but in less volume than formerly. Readjustment is occupying the attention of many plants recently engaged in war work, and the period of settlement in this connection is expected to extend well into the new year. A feature of present activities is the work of machine tool dealers in the purchase and disposal of the equipment used in the manufacture of munitions, not so much in special purpose tools, but in such standard machines as are available. During the past few weeks much of this class of machinery has changed hands. The metal situation has taken on an easier tone, and with the exception of lead all metals are lower.

Steel Becoming Easier

There is every indication that the New Year will open with lower quotations on many lines of steel and iron commodities. While nothing definite has been announced here it has been intimated that Canadian prices will follow in the path of those set in the American mar-

Table Showing Price Fluctuations of Non-Ferrous Metals



kets. The steady easing up in the plate situation has apparently opened the way for a general return to more normal price levels in other lines. While the present volume of business has shown a marked falling off, material is obtainable with considerable less difficulty. Holiday traffic has not affected shipments a great deal and delays from this cause have been relatively few.

Weakness in Metals

Copper demand is steady but light. With the possibility of a lower price or an open market it has made the situation easier and prices this week are 2c lower than last, lake and electro are quoted at 29c and castings at 26½c per pound. Tin is coming through in good quantities and prices here are gradually assuming more reasonable figures; the present price of 80c is a decline of 3c per pound. Spelter is weak and easier at 9½c. Lead is firm but antimony has declined 1c to 11c per pound. A weaker demand for aluminum has lowered the quotation to 43c per pound, a drop of 3c on the week.

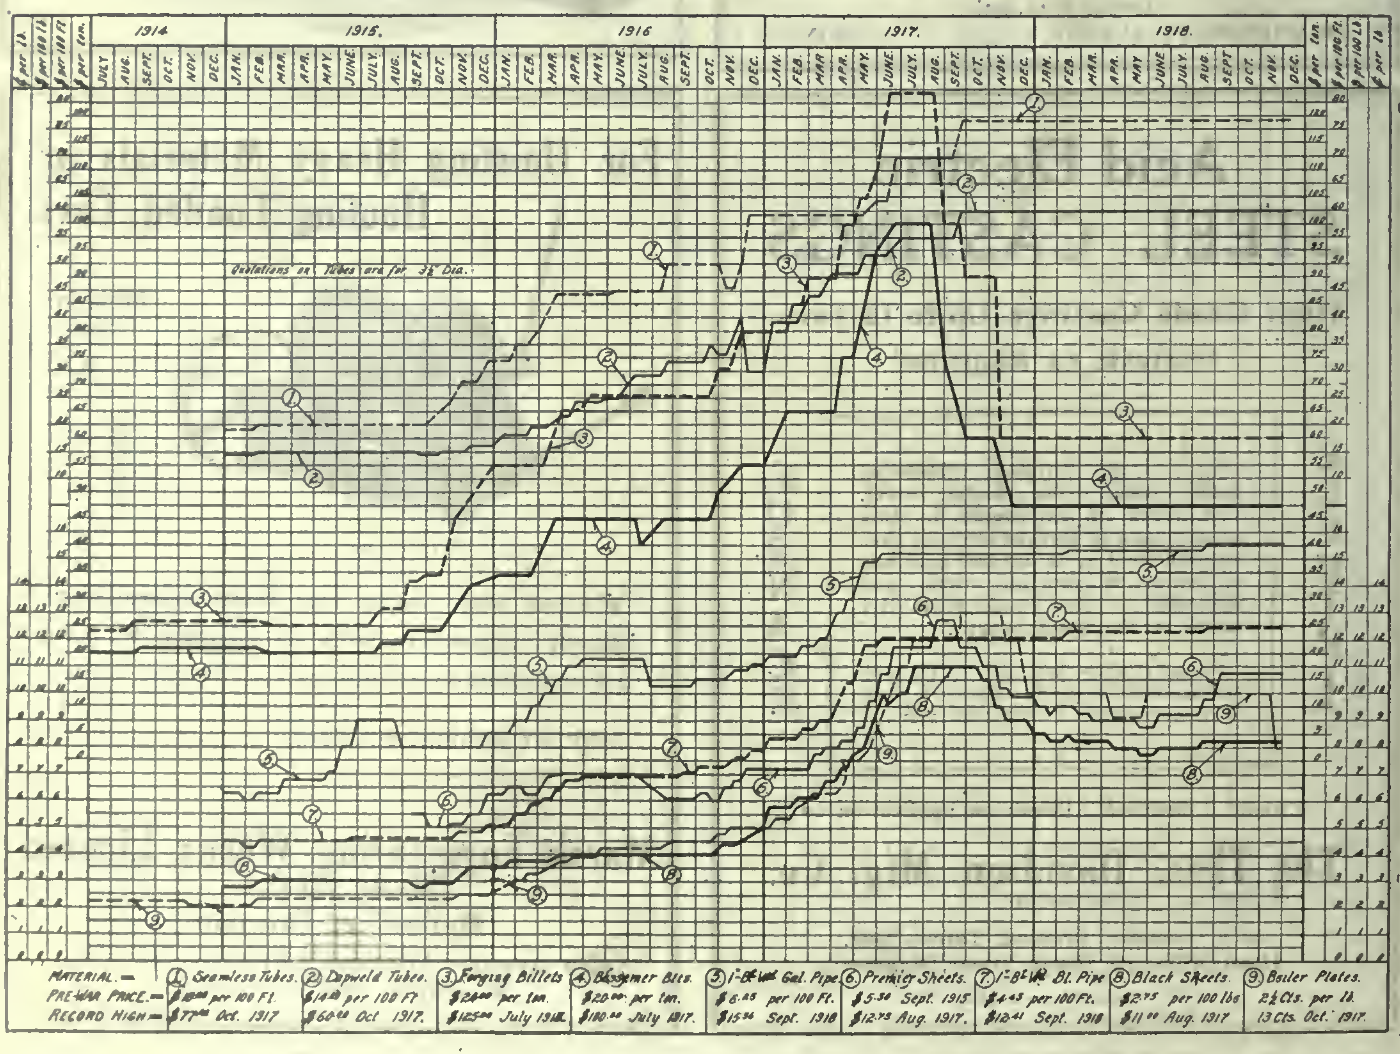
Used Equipment Moving

The volume of business passing through the hands of tool dealers at the present time is not large when compared with that of a few months back, but under existing conditions the demand for tools, especially those that have seen some service, continues to be quite encouraging. Enquiry for new machines is light, but the sales of second-hand equipment is larger than one would think in view of present circumstances. A feature of recent sales has been the disposal of tools to parties that have had shell-making experience and are acquiring a few machines for starting up a small repair shop in some outlying district. Quite a number of sales of this description have been reported, many of them here for small places in the province. One large dealer here reported that the total of cancellations since the war was about $50,000, the bulk of this being in ordered equipment under manufacture. The same dealer has at present on the shelves approximately $5,000 worth of small tools that are virtually useless other than for shell work. In many instances these tools are secured at little better than scrap prices, and the purchasers are able to obtain the tools at a reasonable figure. Quotations on new tools are well maintained, and it is not likely that the decline will be marked for some little time owing to the material and labor costs.

Scrap Market Still Waiting

Nothing has developed during the week to alter the dull trend of the old material situation. The season is one that in ordinary times is marked by inactivity and this year is additionally emphasized by the unsettled conditions incidental to the stoppage of all industrial work in connection with the manufacture of munitions and other supplies. It is, however, anticipated that early in the new year general business will take on more interest, the trade at present apparently awaiting a further softening in prices. While to all appearances the market in common with others is free from control, there is as yet little to indicate that the situation appeals to general trading. One large dealer here has orders on his books for considerable scrap for early 1919 delivery, but buying for this has been deferred until a later date. Changes in price quotations are looked for in many lines very shortly, but present prices are firm but of a nominal character. A decline of $2 per ton is noted in wrought iron axles and car wheels, the quotations being $30 and $36 respectively.

Table Showing Prices for 1918 in Iron, Steel, Tubes, Etc.



"Home Again"

WHEN, in a little shop down on the river front, seven years before the Civil War, this organization was established as CURTIS & CO. MFG. COMPANY, no one could have prophesied that it would continue to exist and grow and outweather three great wars—yet, today the CURTIS plant of nearly 20 acres and over 2,000 employees, and with a national reputation, is a graphic reflection of the CURTIS policy.

When the history of this great world war is written and things can be seen in true perspective, then only will the world appreciate the seemingly impossible accomplishments of the great civilian army of service and support at home, working at the lathe, the bench and the forge, in order that the fighting army abroad might have everything needed to make Victory swift and sure.

From the first days of this war until its victorious close, the CURTIS Company has been in the Service, one of America's Volunteer Industries. While we still continued the manufacture of our regular line, the reserving of our output for Government requirements and essential industries naturally entailed sacrifice and inconvenience to many of our good customers.

Now, with Victory as the nation's reward, and as an organization proud of its war-time sacrifices and accomplishments, we can turn our eyes toward "HOME"—toward the peace-time needs of our regular trade, toward the best adaption of the greater organization and added facilities which are the heritage of our war activities.

Curtis Air Compressors, Curtis Air Hoists, Curtis Cranes and Curtis Single I-Beam Trolleys will be important factors in the rapid and efficient conversion of the nation's war factories in assuming the gigantic work of reconstruction which now must follow. Catalog on request.

Scotia's Output of Coal Decreased During 1918

Labor Troubles Have Made Production on Large Scale Impossible —New Undertakings on the Part of Dominion Steel Corporation —Surplus Labor Being Absorbed in Lumbering Industries of the Province

By F. W. GRAY, Member Institute M. E.

THE coal production of Nova Scotia during the war period, including the year 1918, compares with the maximum production of 1913 as follows:

	Long Tons
1913	7,268,485
1914	6,650,031
1915	6,709,951
1916	6,171,424
1917	5,667,000 (about)
1918	5,175,000 (about)

The production of the larger companies compares with last year and with 1913 as follows:

	1913	1917	1918
Dominion Coal Company	5,120,573	3,916,548	3,640,000
Nova Scotia Steel Co.	813,877	577,171	489,000
Acadia Coal Company	539,121	398,507	280,000
Intercolonial Coal Co.	189,550	179,700	175,000
Inverness Coal & Ry. Co.	293,847	202,719	200,000
Maritime Coal & Ry. Co.	155,051	200,000	180,000
Other Operators	151,466	1 92,355	211,000
Total	7,263,485	5,667,000	5,175,000
Percentage of production from Cape Breton Island	81½%	78%	78%
Reduction from the basis of 1913...	......	23%	30%

The coal consumed in steel manufacture and allied processes was in 1918 approximately 34 per cent. of the total production, comparing with about 22 per cent. in 1913. The amount of coal used at the colliery fires, on the local colliery railways, and in domestic consumption by the workmen, would, in normal times, represent about ten per cent. of the total production, but at the present time it is at least twelve per cent. because of the reduced production being handled by the same equipment that formerly handled much larger quantities of coal. Between 46 per cent. and 50 per cent. of the coal produced in Nova Scotia during 1918 was therefore used by the operating companies in connection with the collieries and the associated steel plants. In Cape Breton Island the amount of coal consumed locally is proportionately greater because of the location of the steel plants in the Island. It will run close to sixty per cent. of the total production.

Falling Off In Production

At the outbreak of the war, roughly two million tons of coal per year was being shipped from Nova Scotia—chiefly from Cape Breton Island—to St. Lawrence ports. In 1917 not more than 50,000 tons were sent up the river, and in 1918 no coal at all reached the Montreal market by water, although a negligible tonnage was sent by rail to points in Quebec from the collieries at the extreme western end of the province.

A perusal of the tabulation given above will show that the decline in outputs has chiefly affected the larger companies, and there has been an increase in the aggregate output of the smaller operators. A number of new openings into crop areas, or easily accessible areas that are unprofitable in normal times, have been made, and a tonnage of coal has been secured that has greatly assisted in supplying local needs. These enterprises have been occasioned by unusual conditions of coal shortage and high selling prices, and they cannot be regarded as permanent additions to the productive capacity of the Province. They will disappear when the conditions that have brought them into existence pass away.

Prospects None Too Bright

The outlook for the coal industry is not hopeful. The reduction of almost one-third in output has not been accompanied by a corresponding reduction in the number of workmen employed, because the shortage of men that has brought about the reduction in outputs is confined to the producing or miner class of employee. Wages have advanced from 75 per cent. to exceeding 100 per cent. over the basis of 1916. Materials have advanced correspondingly in price. Overhead expenses have increased during the war period because of the decreased ratio of production, but also because of the addition of new imports in the nature of taxation, local rates, a Provincial Workmen's Compensation Act, and the alteration of the previous system of fortnightly pays at the collieries to weekly pays. This last named alteration has largely increased the clerical staffs at the collieries. Physical conditions of extraction are also becoming yearly more difficult, because of the larger percentage of submarine coal that is being mined, and must in future be mined if the production is to be maintained.

Not Getting The Results

The factor that is at the present time reacting most detrimentally on the industry is the inefficient nature of the colliery working forces brought about by the unduly small percentage of men working at the coal face. If the number of miners actually digging coal can be restored so as to properly balance the auxiliary workers engaged in the handling and preparation of the coal, then simultaneously production costs will be lessened and production will increase.

Wages of miners were increased at the beginning of 1918, and again on the 1st of July, and it is intimated that a further increase is to be asked by the workmen effective on the 1st of January. As the maximum selling price for coal allowed by the Fuel Controller is already in several instances lower than the cost of production, it does not seem possible that further increases in wages can be granted, and it will be difficult for the miners to justify their request on the ground of the increased cost of living now that hostilities have ceased and the process of deflation in values should become operative; apart altogether from the conclusive fact that operators cannot spend more on production than they receive for the coal sold.

Predictions Came True

In the writer's review of the coal and steel industries, which appeared in CANADIAN MACHINERY last year, it was stated that some of the less remunerative collieries would be compelled to cease operations. This did actually happen during the year, and it is possible, indeed probable, that other collieries in Nova Scotia must cease operations during 1919, unless either the costs of production are markedly decreased or much higher selling prices are obtainable than is the case to-day.

The Amalgamated Mine Workers of Nova Scotia have declared their intention to affiliate with the United Mine Workers of America. It is quite certain that the coal operators will object to this as they did in 1908-9, and in order to stoppages of work as at that time took place, it is stated that a confernce is being arranged between representative operators of the province and leading officers of the United Mine Workers of America to arrive at some understanding.

Speaking generally, the prospect before the coal trade in Nova Scotia is very troubled. There seems very little reason to expect any increase in coal production, although it is understood that the military authorities propose to release a number of Nova Scotian miners at an early date, and these men should help production, always provided they are skilled workers, because, as has been pointed out, there is already a surplus of non-productive labor at the collieries. It is probable that the return of miners to the collieries will serve to offset and

arrest the declining tendency of the outputs, but this is probably the best that can be hoped for, and it may be anticipated that the production of coal in Nova Sotia during 1919 wil not exceed the figures of 1918.

The Steel Trade of 1918

Tne course of the steel trade during 1918 has been marked by a gradual lessening of activity in the manufacture of shells and shell steel, and an increase in ordinary business. This tendency preceded, and to some extent foreshadowed, the coming of the armistice, and it has served to lessen the severity of the readjustment which is now taking place. A period of uncertainty is now being experienced, and some definite and vigorous leads from the Government will be required to carry the workers through the lean months that seem likely to intervene between the cancellation of munitions orders and the booking of commercial orders under the unaccustomed conditions of an open market. It seems to be generally felt that the necessity and the demand for steel and steel products exists and must be filled, but there is a hesitancy in business that may lead to demoralization and unemployment, while employers and customers are waiting for something to turn up, unless a vigorous leadership is given by Ottawa. The whole resources of the nation in manpower and material have been monopolized by the Government during the war period. The initiative of the corporation and the individual has been largely destroyed, and the Government having assumed control of industry under admitted national necessity, must also undertake to reverse the wheels of control until such time as corporate initiative and the operation of natural laws of supply and demand can be recovered. There is no magic in a Government, nor can it perform miracles, but, if under the stress of necessity, a Government leads the country along an extraordinary course, it must also, under the stress of equal necessity, guide the country back into ordinary and maybe humdrum paths.

New Equipment Added

Enlargement of plant and new construction during 1918 includes the completion of two batteries of Kopper's bye-product coke-ovens for the Dominion Iron & Steel Cmpany in Sydney, and the completion of the reconstruction of No. 1 Blast Furnace. The erection of the new plate-mill is proceeding, excavation work being completed and foundations well advanced. The erection of this large plate mill at Sydney marks a stage in the progress of this country towards national self-reliance, and is a logical addition to Canada's steel industry. It is a courageous proceeding, and is perhaps a better illustration of Government than of corporate initiative. The Government, having been so largely responsible for the erection of this mill will naturally be required to foster its commercial success, and this is one illustration of how Government initiative and interest, originating in war-time measures, must be continued into the less exciting times of peace.

The Nova Scotia Steel & Coal Company completed a new blast furnace at Sydney Mines, intended to serve as a spare furnace, but it has not yet been found necessary to place the new furnace in blast because of the unusual length of service being obtained from the lining of the older furnace.

The outlet for steel products, now that the necessity for munitions steel has disappeared, is expected to come largely from the requirements of railway and water transportation, on both of which great inroads have been made by the interruptions of supply and the wastage occasioned by the war. The Dominion Iron & Steel Company has been rolling railway rails to the order of the Canadian Government since early in the year. The Nova Scotia Steel & Coal Company have during the year completed the building of the SS. "Watouka," making the third steel vessel which has been built at New Glasgow during the war. It is understood that two more steel vessels of 2,800 tons each are to be immediately laid down at New Glasgow. The "Watouka" was launched during the early part of December and is now fitting for sea.

It is anticipated that orders for freight cars will be received by the Eastern Car Company from the Government in the near future that will enable this plant to operate successfully for some time to come.

Since the signing of the armistice there has been a large readjustment of employment in the neighborhood of New Glasgow, and between 800 and 1,000 men have been released by the cancellation of munitions orders at the Trenton plant and in the numerous small shell plants that were centred in Pictou County.

Surprisingly little disturbance of labor conditions has been occasioned so far by this adjustment, which is probably owing to the fact that the labor employed in munitions manufacture was largely drawn from the surrounding country districts, and the workmen have returned to their homes, and have to some extent found employment in lumbering operations.

While there is an underlying feeling of optimism regarding the future of the local steel industry, because of the general soundness of Canada's industrial position, and the feeling that the restriction of building operations, of railway extension and upkeep, and the development of public and corporate works, that was imposed by war conditions during four years past, must have created a demand for steel in various commercial forms that will eventually manifest itself just so soon as business confidence is restored, it is evident that there will be a pause between the cessation of work on war orders and the commencement of work on regular commercial lines that can only be shortened by a judicious fillip administered from Ottawa.

Steel is King When the Nation Goes to War

Industry Was All Marshaled For Winning of the War—The Trouble Was in Locating the "Bottle Neck" and Keeping Stopper Out—Investors Waiting For the Prices to Come Further Down

By B. E. V. LUTY, Pittsburg Correspondent of CANADIAN MACHINERY

PITTSBURGH, Dec. 26.—A keynote thought, which will serve at once to explain much that developed in steel distribution during the war, and also to furnish a line on the situation produced when the war closed is this, that steel is the basis or backbone of modern industry. It is not primarily or chiefly a weapon, but rather performs important functions in nearly all the activities that are essential in conducting modern warfare. The idea that steel is chiefly a weapon, offensive or defensive, is a relic of the middle ages, when the armorer was more important than the blacksmith.

That there is much to explain about steel's connection with the war is obvious. One is entitled to an explanation, for instance, or how it was that priminent steel men, some of the brightest and most broadminded in the industry, were engaged for several months after the United States declared war, on April 6, 1917, in attempting to make estimates of how much steel would be required for war purposes. These estimates, which the writer endeavored at the time to follow carefully, ranged from 10 to 35 per cent. of the total output. The mental attitude, moreover, was that this amount of steel was going to be subtracted from the general supply, so that, once the percentage was determined, as many men thought they could do, one would be able to see how scarce steel was going to become. If the proportion was only 10 per cent., the difference might not be noticed, but if it was as much as 35 per cent.. then steel would become very scarce for peace purposes.

Why Steel Was Scarce

In the retrospect all this looks foolish, but equally foolish appraisals as to the future will be made if the fundamental or keynote principle is not faced squarely, that steel is the basis of modern industry, and industry was all marshaled for winning the war. Steel was very scarce during the war, but it was not scarce simply because a large tonnage was shot away in the form of shells, or went into gun manufacture. The coal mines worked as never before, and used much steel. Many cars and locomotives were built. Public service corporations were strained to furnish more current than ever before. Tools of all sorts were in great demand for carpenters, blacksmiths, machinists, and all trades. Tremendous quantities of machine tools were required. Motor trucks and passenger cars were required. These are all peace goods. Airplanes were not commercial before the war, but they are now, for during the war the United States Post Office department established one aerial mail route and lately it has established another, with others to follow.

It took a long time, as a matter of fact, for it to become clear that all steel was needed for winning the war simply because it was not realized that practically all industries were going to be put in line to help. Late in 1917 some of the steel producers felt that within a short time steel would become plentiful, because, apparently, so many of their customers would have reduced demand.

B. E. V. LUTY

When steel production was so greatly curtailed by the transportation breakdown last winter these observers felt that the time for steel to become plentiful was merely postponed two or three months.

What occurred was that while many customers of the steel industry lost much of their ordinary business, the Government gave them orders requiring the same goods they had previously been making, or goods merely of a slightly different description, and they became customers of the steel industry again.

The Pressure Was Applied

J. Leonard Replogle, director of steel supply, was continually calling for more steel. About April 1, 1918, he redoubled his efforts and insisted to the steel producers that they would drop all considerations but that of furnishing steel for winning the war. At a meeting of the steel industry, April 26, a "100 per cent. efficiency pledge" was taken. The War Industries Board then proceeded to take complete charge of the production and distribution of steel. On May 17 a joint committee of the board and of the industry was appointed to study the whole matter on a practical basis. June 6 the board promulgated comprehensive regulations, greatly extending the priority list and establishing, to follow the priorities, a "list of purposes entitled to preferential treatment." If any steel should be left it would fall into what was afterwards designated as Class D, and could be shipped for purposes not designated as essential, upon the securing of a written permit from the Director of Steel Supply. It became clear that the chief function of this regulation was to discover steel for which there was no designated use, whereupon the War Industries Board would divert it to some priority or preference use.

Tremendous Amount Asked For

The Director of Steel Supply first estimated the steel requirements for the second half of 1918 at 20,000,000 net tons in the form of finished rolled product, while he claimed the maximum production attained in any half year had been only about 16,500,000 tons. Later he raised the estimate to 22,000,000 tons, and still later expressed the belief that the requirements would more likely prove to be 25,000,000 tons. Just here it is interesting to note that if production in December were at the same rate as in November the half year's output would be about 18,500,000 net tons, thus it is evident that the supply was not equal to the programme mapped out. The steel desired for all the more important uses had been estimated at the maximum that it seemed possible to use, and it did not prove possible in all cases to use the maximum. A chain is as strong as its weakest link, but in designing the war chain the effort was made to have each link as strong as possible. Thus, in shipbuilding, there was pressure for a supply of steel for the rapid putting of steel into hulls, and for a maximum supply of boilers, engines and other appurtenances. As time passed it developed that the weakest link in the chain was the supply of equipment. Hull launchings ran far ahead of vessel completions, and steel accumulated between the plate mill and the shipway. To change the simile, the "bottle neck" was the supply of equipment, but no one could have told in advance that it would be there rather than somewhere else. Without so much pressure for steel the bottle neck might have been there instead. In the matter of shells there were corresponding experiences. Early in 1918 the bottle neck was in forging capacity for large shells; later, with a large increase in forging

capacity there was a good supply of forgings, and there was one time when, on account of shortage of shell steel, where the bottle neck appeared to be temporarily, supplies to certain forge shops were curtailed, but the machine shops had supplies of forged material up which to draw.

No Famine in Domestic Lines

Reverting to the fundamental idea that steel is the basis of modern industry, and nearly all industries were called to the colors, so to speak, it becomes plain that the end of the war could not find the country bare of steel all along the line. The chief customers of the steel industry had been well supplied with steel. It was not the direct customers who had been denied steel. His customer, in turn, may have been denied the finished product, and that is where the scarcity, if any, would develop. Lawn mowers would have become very scarce because the lawn mower factories were expected to turn out something useful for the war. Stoves for the civilian population became somewhat scarce, though the effect was barely noticeable, because stove factories were making stoves for the Government. Stocks of steel in jobbers' hands were strictly controlled, and the civilian population could not get their usual supplies. Automobiles did become very scarce, while the demand continued. The result was that when the armistice was declared and the restrictions on the manufacture, distribution, and consumption of steel were removed, the chief new demand that came to the steel trade was from the jobbers and the automobile manufacturers. Other customers continued to require steel, but at reduced rather than increased rates.

With the great majority of consumers of steel busy helping to win the war in one way or another, and many of them supplied with more steel than usual rather than less, one may ask how it was possible to find also the steel that was used directly in warfare, for there was a large tonnage so used, for shells, guns, transportation in France, warehouses on both sides the Atlantic and for the extensive shipbuilding programme.

Where the Axe Was Applied

Where was this steel found? It was found by the almost complete stoppage of construction work that was considered unessential. Now in normal times perhaps half, probably considerably more than half of the steel produced goes into permanent construction, in other words into investments. A clear distinction must be made between the two uses of steel. No exact line can be drawn, but broadly speaking the distribution of steel in normal times involves two classes, the first represented by things like the following: Tin cans, tools, household utensils, repairs, etc., etc.; and second, bridges, office buildings, hotel buildings, factories, public service establishments, railway rolling stocks, etc., etc. Consumption along the first line continued, while consumption along the second line was practically cut off, except where the war required it.

While the War Industries Board placed a ban upon building, however, it must not be thought that otherwise building would have continued to any extent. High costs all along the line furnished their own damper, and the War Industries Board with its prohibition merely caught what was left.

When Will Costs Come Down?

The question now is, when will costs be such that investments will be undertaken? We have seen that the ordinary consuming industries were not, in the main, starved as to steel, but rather were fairly well supplied. Some of them will require less steel, at least for a time. The steel that ordinarily goes into investments was diverted to direct war use. The investment buying must return. The demand for steel is already light, and it will grow lighter, week by week, as those whose accumulated wants are filled. Some observers in the steel trade think production may drop to 60 or 70 per cent. of capacity, perhaps before the new year is many weeks old. Almost everyone believes that eventually there will be a very heavy demand for steel, but that will come only when the investor has come into the market.

This matter of the investor is a very complicated one. The investor thinks only of the total cost of his investment. Taking the average or typical investor, and considering him broadly, whether he is the head of a new enterprise or merely a subscriber to so many shares of stock, or whether he is a municipality contemplating improvements, or an existing corporation thinking of making an extension, the investor thinks of the total cost of the investment, of which more anon. He must set this estimated cost against two things, first, the pre-war price that his competitors had for a new factory or a new hotel or office building will have to compete with those already in existence, and second, the prospective cost of the same investment six months, one year, or two years later. If 10 per cent. of the capital can be saved by waiting six months, or 20 per cent. by waiting a year, the best thing to do is to allow the money to lie at interest until it will buy more. Suppose for argument, that costs are never going to come down, that is not sufficient to start investment buying. The investor must first assure himself that with his high cost investment he can compete with the lower cost investment already in the field. Next, he must be convinced of this fact that costs are not going to come down. Professor Smith, the eminent economist, or John Jones, president of the Blank Steel Company, may be convinced, but if Joe Brown has the capital it is Joe Brown who must be convinced.

Many Costs Make Up Total

Now as to the cost of the investment. Mr. Brown considers it as a total. The ordinary investment, that involves the use of steel, requires also the purchase of many other materials and also the employment of much labor. If the total cost has to come down it is not sufficient for the price of steel to come down. Prices of the other materials must also come down before the investment is made if they are going to come down at all. If labor cost is to come down it must also come down before the investment is made. This labor cost is made up of two elements, the basic rate of wages per hour or per day and the amount of service rendered per hour or day. Many employers complain much less of wage rates than they do of the indifferent performance of labor.

Steel prices have come down a trifle and will probably come down more, but that is only one element, no one needs to worry much about the price of steel. The American steel makers are intelligent and will face the situation. They will not be the stumbling block to a resumption of investment buying and they may have considerable room for reducing prices. The reductions in steel prices just made as a readjustment measure make an average, considering all important finished steel products, of about $4.25 per net ton. For the first three-quarters of 1918 the Steel Corporation made deductions for war taxes amounting to between $17 and $18 per ton. and still showed large earnings left. Taxes for 1918 will be lower. As to wage cost, there is room for considerable decrease if the men will work harder, work as they formerly did, without reducing the hourly wage rate. The latter may come or may not, but the former will come.

Halifax.—Owing to the delay in steel shipments from the United States the keels of the first ships to be built in the Halifax Shipyards, Limited, will not be laid until late in January. It had been hoped to lay them this month.

Seattle.—The Northern Pacific district has delivered to the Emergency Fleet Corporation of the United States, between August, 1917, and the end of November this year, no less than 800,000 deadweight tons' capacity in ocean-going steamships. This output was divided between three ports, Seattle, Portland and Tacoma. The number of steamships delivered was 96, made up of 56 from Seattle, 33 from Portland, and 7 from Tacoma.

IRON AND STEEL TRADE IN 1918

THE history of the Iron and Steel Trades during the year 1918, as in the two preceding years, will to most of us read like a romance. While all the Canadian and American mills were last year taxed to their utmost capacity, it is noteworthy that prices were lower than in the two previous years. In 1916 and 1917 prices ran riot—there was no controlling influence, and prices were governed simply by what buyers were willing to pay. It is recorded that steel plates touched 15c per lb. base at the American mills, and tin plates were also sold at $18.00 base at the works. These are record prices. Then came the regulating of prices by the United States Government, when America came into the war, and immediately everything came down to a settled basis. We must remember, however, that the fixed prices applied only to the domestic markets in the United States. The export market was open, and ordinary buyers in outside countries, Canada included, had to pay much higher prices for their requirements. Then came export licenses, priorities and what not, until the most of us gave it up in despair, and had to content ourselves with business which could command high priorities on certain schedules adopted by the American War Board. Dealers were occasionally allowed to import a certain quantity of material for stock under special conditions regarding distribution, but they had to receive authorization from Ottawa before a single plate or tube could be delivered to consumers, even for the most pressing work.

The strain is at last over, and while licenses are still necessary for the export of certain classes of goods from the United States, there is no doubt that conditions in this respect will become normal in the course of the next few months.

The next question to be considered is the probable course of the market over the first quarter of 1919, for it would be idle to hazard any opinion for a later period. Taking into account the present high cost of production, due to high wages and raw materials, it appears to me that present prices on most of the staple articles of iron and steel are extremely reasonable, and afford only a fair profit to manufacturers. Wages will not be reduced by any concerted action on the part of the employers; indeed it would be unwise to attempt any reduction. This must be left to the ordinary economic law of supply and demand, and as the cost of living decreases, so will wages gradually recede to a more reasonable basis, for no one denies that in certain branches of work they have been excessive.

Raw materials, such as ore and fuel, have been contracted for at present prices for the coming winter, so that no reduction of consequence can be made on that score. These conditions apply to the United States as well as to Canada, therefore I can see no reason for any radical decline in prices during the first quarter of 1919, at least. It must be remembered also that stocks in dealers' hands have been reduced to a minimum, owing to the difficulties of securing supplies. I look, therefore, for a fairly reasonable business during the coming winter, and at the end of the first quarter we can revise our ideas on the basis of conditions then prevailing.

Consequent on the ending of the war and the stoppage of the making of munitions and war supplies, certain orders and contracts have necessarily been cancelled, but there has been no desire to cancel orders for general supplies for delivery during the next few months. In any case, it would be extremely unwise either to ask or to accept such concellations. It is very doubtful if buyers could replace their orders at lower prices for some months.

In view of all these facts, I think manufacturers and dealers may look forward to the next few months without anxiety. Business will necessarily be less, but this must be expected, and there will be a welcome relief from the strain under which we have been working during the past few years.

J. T. McCALL.
Vice-Pres. and Gen. Mgr.
Drummond McCall & Co.

Montreal, December 12, 1918.

Canada Cotton Co. Extends.—Work connected with adding another story to the dye house of the Canada Cotton Co., Hamilton, will probably be started at an early date. Many other plants have additions to their buildings in view, according to a report of Building Inspector Whitlock.

Montreal.—A motion is before the Exchequer Court, Mr. Justice Audette presiding, for the purpose of fixing the value of the use and occupation of the McCarthy Shipyard at Sorel by the Canadian Government since December, 1915, at $30,000. The owners fix the value of use and occupation at $80,000.

Rochester, N.Y.—The tug Laura Grace was driven ashore at Grandview Beach off the port of Rochester on Friday morning. The captain, eight men, and one woman reached shore safely in a small boat, and one man was rescued by a United States tug. The Laura Grace left Kingston on Thursday night and ran into a storm, with the result that after an all night battle with the storm the captain lost his bearings and did not find them again until the tug went ashore.

Midland.—No less than twelve boats of the Pittsburgh Steamship Co. will spend the winter at Port McNicoll and Midland. It is unusual for the steamers to use the Georgian Bay ports for this purpose. The boats are each of at least 600 feet long and 12,000 tons carrying capacity, and each ship has at least 480,000 bushels of grain, making a total of 5,760,000 bushels, which will be unloaded during the winter and shipped to Europe. One of the steamers has the largest cargo ever shipped from Duluth, 482,000 bushels, which is now at Port McNicoll.

Collingwood.—The steamer Chester A. Congdon, which went ashore at Chester Rocks, near Passage Island, at the Canadian head of Lake Superior, has the distinction of being the greatest single loss recorded in the lake trade. The steamer and cargo were valued at $1,500,000, the steamer being insured for $750,000, and her cargo, consisting of 380,000 bushels of wheat, valued at $2.35 a bushel. The Congdon was formerly the Salt Lake City, built in 1907, and her tonnage was 10,300 d.w. She was owned by the Continental Steamship Co.

The Following Used Plant and Machine Tools :

CRANES

LOCO CRANE, to Lift 20 Tons at 35ft. Radius. Boiler Pressure, 80lb. Gauge, 10ft. 9in. Power-driven in all motions. Has Fast Whip for Loada up to 2 Tons.

ELECTRICALLY DRIVEN FOUNDRY TYPE CRANE, to Lift 50cwt. at 30ft Radius. All motions power-driven. Complete with Motor, 250 Volts, D.C.

10-TON STEAM DERRICK CRANE, Steel Mast, Double Timber Jib, 60ft. long. Engines and Gearing in excellent order.

3-TON STEAM DERRICK CRANE, Double Timber Jib, 45ft. long. Makers, Gibson & Napier.

LATHES

FIVE No. 56 CLEVELAND AUTOMATIC FOUR-SPINDLE LATHES, taking Bars up to 2in. Condition as New.

POWERFUL TREBLE-GEARED S.C. LATHE, 26in. Centres, takes 25ft. between Centres, swinging 7ft. in Gap. Overall Length, 38ft.

HOLLOW SPINDLE CAPSTAIN LATHE, taking Bars up to 2in. Fitted with Quick Bar Rlease Motion. Condition as New.

DRILLING MACHINES

D.G. RADIAL DRILLING MACHINE, 4ft. 6in. Arm, 2½in. Dia. Spindle.

D.G. RADIAL DRILLING MACHINE, 3ft. 6in. Boring Radius, 2in. Dia. Spindle, which has Quick Release Motion.

D.G. RADIAL DRILLING MACHINE, 4ft. Arm, Rising and Falling, 2¼in. Dia. Spindle.

VERTICAL DRILLING AND TAPPING MACHINE, Balanced Spindle 2½in. Dia. Compound Table.

HORIZONTAL BORING MACHINES

DOUBLE STANDARD DRILLING AND TAPPING MACHINE, 3in. Dia. Spindles, Drilling 30in. Deep, Power Feeds to all motions.

POWERFUL MOTOR-DRIVEN DRILLING MACHINE, by Shanks. Two Spindles, 3¾in. Dia., with 36in. Travel. Reverse on both Spindles and complete with Motor.

HEAVY TYPE DOUBLE STANDARD BORING AND DRILLING MACHINE, 4½in. and 5in. Spindles, 3ft. Travel. In excellent order.

PLANING MACHINES

RACK-DRIVEN MACHINE, by Loudon. Capacity, 12ft. by 5ft. by 4ft. Twn Tool Boxes on Cross Slide. All Feeds Self-Acting.

RACK-DRIVEN MACHINE. Capacity, 8ft. by 3ft. by 3ft. Two Tool Boxes on Cross Slide. Makers, Hulse & Co.

RACK-DRIVEN MACHINE, 6ft. by 2ft. by 2ft. Single Tool Box on Cross Slide.

SHIPYARD PLANT

30ft. PLATE EDGE PLANER, Swivelling Tool Box, Hydraulic Rams. Makers, Smith Bros.

18ft. PLATE EDGE PLANER, by Bennie. Open Ends. Condition as New.

PUNCHING AND SHEARING MACHINE, to Punch and Shear 1in. Plates. 23in. Gaps.

PUNCHING AND SHEARING MACHINE for 1in. Plates. 22in. Gaps, with Angle Cutter to cut up to 6in. by 6in.

DOUBLE-ENDED PUNCHING MACHINE for 1in. Plates, 24in. Gaps.

BENDING BLOCKS, 4ft. by 4ft. by 6in. Dog Holes, 1⅝in. Dia.

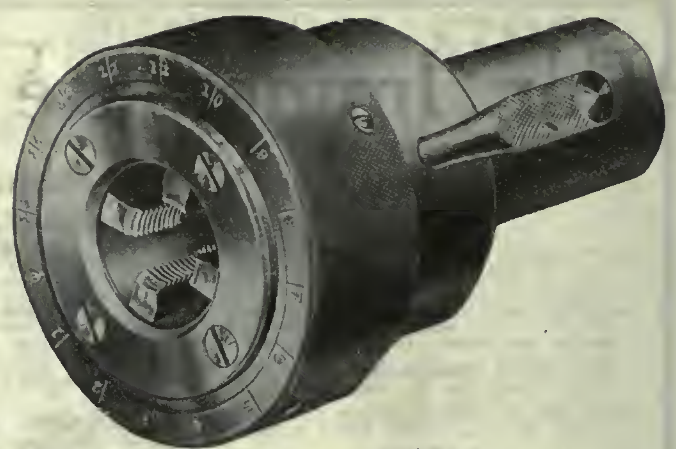
MURCHEY



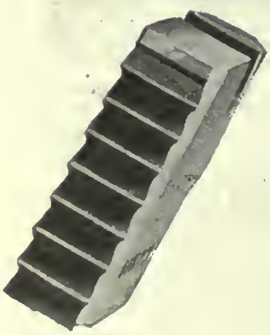
COLLAPSING TAPS AND SELF-OPENING DIES

Clear Free From the Thread

Instantly

—an action that prevents all danger of stripping, besides making a remarkable reduction in cutting time.

The result is closer accuracy and greater quantity.



Murchey Tools are economical, too. They last longer than solid tools and when worn you need merely change chasers. One chaser can be quickly reground while another is in use.

Murchey Service will enable you to speed up production immeasurably on your tapping machines, drill presses, monitor machines, boring mills, turret lathes and on all machines on which taps and dies are attached.

Write for full particulars.

Purchase in Canada

Quality

Service

TO UPHOLD THE GLORY we have justly earned—to honor our noble dead—to comfort the wounded, and extend to the men returned the hand of prosperous welcome, we must cast aside all forebodings and face the future with unbounded courage and confidence and, without a shadow of doubt, declare to the World that this Nation, which was so quickly and successfully transformed to a War basis, can be depended upon to revert to Peace conditions with equal success.

THE BUYER AND SELLER must recognize their duty to the Nation and co-operate fully to the end that all products that can be produced in Canada by Canadian workmen shall not be purchased elsewhere.

OUR DUTY IS PLAIN: Canada with Canadian labor and capital can produce, manufacture and distribute products sufficient to keep the wheels of industry turning to the limit. The song of Prosperity and Happiness should ring out all over the land. Let us sincerely pledge, to the extent of our needs, to purchase materials produced in Canada by Canadian Workmen, and the result of our efforts will return to us the Blessings of a Prosperous and Happy Nation.

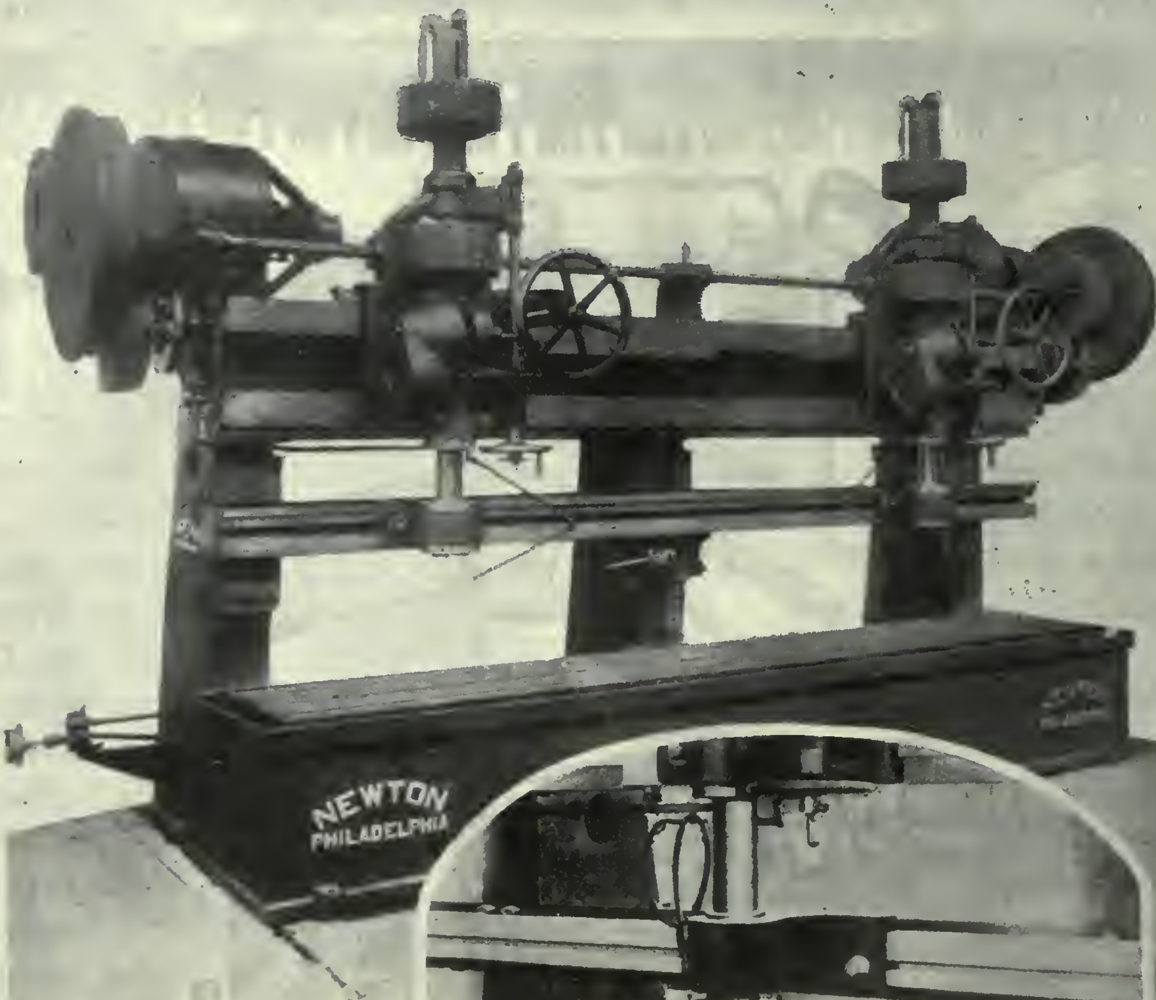
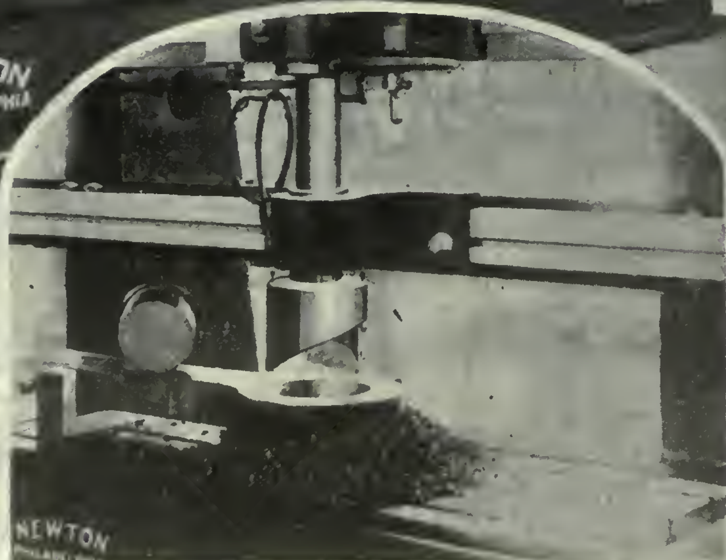
NEWTON

SYSTEM FOR LOCOMOTIVE ROD BORING





To date we have made 17 installations and are now building sufficient machines to satisfy the requirements of 9 major arteries of traffic. Advantages:

1—Newly-developed hollow cutters dispense with the necessity of drilling pilot holes for boring bars. Drills, material, time and power are, therefore, conserved.

2—Kerf by cup cutters, in no case, exceeds ⅝".

3—Cores removed solid have a tremendously increased salvage value.

4—The exclusive NEWTON lower support makes these economies possible.

5—Two ends of one or one end of two rods are bored at the same time.

6—Twin spindles allow duplication of center distances in like rods.

7—Cross-heads may be reamed to advantage.

8—Odd jobs of heavy drilling may be done with dispatch.

RICE LEWIS AND SON
LIMITED

ESTABLISHED 1847 TORONTO, ONTARIO 19 VICTORIA STREET

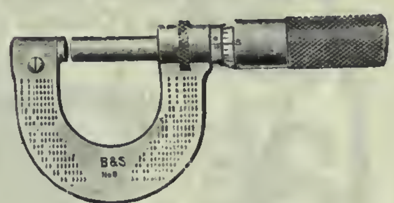
Machine Shop and Foundry Supplies for Greater Peace-Time Output

No one better than you, Mr. Manufacturer, knows that competition in the days to come will be keen. Better materials and more efficient tools make for quantity output—and profit.

Ask for Quotations on Iron and Steel

We have in stock for immediate shipment the highest grade Bar Iron, Black and Galvanized Sheet Iron, Machine Steel, Cast Steel, High Speed Steel, Cold Rolled Steel, etc.

Micrometer and other fine tools



Select from such wholly dependable makes as Starrett or Brown & Sharpe, or from other makes you have proven in your own shop to be most durable and efficient. Our stocks are complete.

CRESCENT BELT FASTENERS

Clinch beneath the surface of the belt on the pulley side—no part in contact with the pulley. They maintain uniform grip the entire width of belt and never weaken from wear.

Machinist's Tool Chests

Time and again skilled machinists have remarked on the strength of construction and compact design of our Tool Chests. Have us give you full particulars.

"Victor" Hack Saw Blades for Tough Metals

Durable, fast-cutting blades that you can rely upon to cut true through toughest metals. Users have found that these blades increase every day's output and serve much longer than ordinary blades.

Write us about your requirements.

RICE LEWIS & SON, LIMITED

FORBES

PIPE CUTTING AND THREADING MACHINES

The One-Man Way

WHERE the old stock and die method of pipe cutting and threading required two to four men for each operation the FORBES Pipe Cutting and Threading Machines require but one man.

Nothing larger than 4 inches is ever attempted with a stock and die. One man with a FORBES can cut off and thread all sizes of pipe up to 15 inches. A boy can operate a FORBES on the smaller sizes of pipe with ease and efficiency.

Every FORBES is fully self-contained, and can be carried right to the scene of operations.

Owing to the simple design of Forbes machines which eliminates the necessity of turning heavy lengths of pipe, they require much less power to operate, occupy half the floor space and cost far less than the ordinary type of lathe bed machines.

Whether hand-operated, motor-driven, or combination hand and power, a FORBES Pipe Cutting and Threading Machine is a simple, labor-saving, cost-cutting ONE-MAN operation.

Write for the full details.

One Great Advantage

which the Mueller Radial Drill has over other radials is its Patented Stationary Column.

Note its strength—one-piece and stiffened by four internal webs.

Note the fact that every control lever is within easy reach of the operator.

Note that its entire structure is firm, rugged and capable of enduring stress and strain.

Note the fact that users throughout the country are increasing production speed through its use.

SIDNEY

17 and 19 inch

High Duty Engine Lathe

Entire quick-change gear mechanism mounted on the front of bed, and fixed permanently in accurate alignment by a tongue and groove, is a complete unit in which every gear is made from high carbon steel. The cone gears, because cut with improved 22½ degree angle cutters have pointed teeth slightly rounded at the top—the only gear in tumbler gear mechanism that can and does make instantaneous engagement without interference.

Bed of 25% steel mixture has heavy double wall cross girts, two feet apart. Its rigidity is great, because ordinary construction would not stand up under strain of such speed and deep cuts as this Sidney Lathe is capable of making.

Write for Bulletin that fully describes this big-earning Sidney Lathe.

Champion Vise

BULLDOG JAW AND A BULLDOG GRIP

The "CHAMPION" TOOL HOLDER grips the cutting tool with bulldog tenacity. Note the heavy extended lip which protects the tool. This holder stands up under the heaviest service. It can effect a distinct saving for you in breakage. A further saving is effected with this holder, since it can use up the small ends of cutters. High Speed Steel is expensive and difficult to obtain. Better economize your present supply—make it last longer and turn out more work by using "Champion" Tool Holders.

"CHAMPION" EXPANDING MANDRELS

They have no claws—cannot injure work. They are simple, accurate and low in cost. A complete set as shown makes any size mandrel between ½ and 6½ in. immediately available. They are the ideal equipment for economy in first cost and for the production of accurate work.

SHOP FURNITURE

Including Portable Benches, Steel Racks, Tool Stands, Trucks for moving boxes, heavy castings, etc., Lathe Pans, Steel Boxes, etc., etc.

The "CHAMPION" VISE will easily handle any odd-shaped work as well as ordinary shapes. It is more quickly positioned than any other vise. The work can be kept in proper position before the eyes of the workman in the best light without the necessity of stooping or other tiresome and awkward attitudes at the bench. A long stride toward correct work. Simple—Durable—Accurate.

WALLACE Bench Planer

"Speeds Up" Production Cuts Cost

THE bulk—or about 70 per cent.—of your fitting, trimming, jointing or surfacing is on work less than 4 feet long and 4 inches wide. For lack of better facilities you have had to **do** all this work by hand—at an enormous cost. If every operation were as costly you'd close up shop. You can't afford to run to the big stationary jointer with each piece of work —yet that cost must be cut.

THE Wallace Bench Planer was designed especially for small work. It is the quick action machine you need to turn out that bulk of your planing, surfacing, beveling, jointing and fitting efficiently—economically. That's why it's busy in the General Electric, Westinghouse, Reaser Furniture, Long Furniture, Brunswick-Balke-Collender, National Malleable Casting, Pierce-Arrow, Jackson Sash and Door, and hundreds of other shops, from the biggest to the "one man" cabinet, pattern, carpenter shops, etc. In many shops it takes care of **all** the work.

It is portable—works right on the bench—handy at the elbow of your men.

Try this remarkable, simple, cost-saving machine. Stop those daily losses!

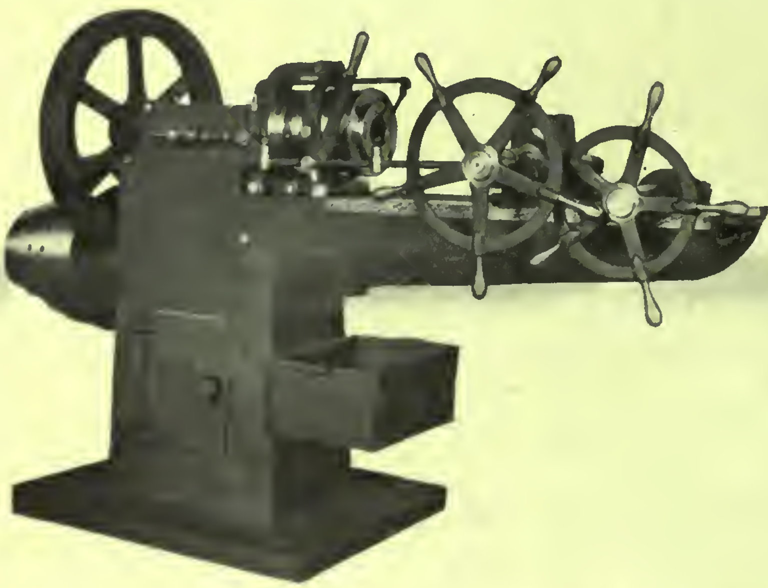
For cleaning castings or surface work of any kind. Made in four sizes, ¼ to 2 H.P. Weight from 18 pounds up. Guaranteed for hard usage.

Standard Bolt Cutters



As a result of twenty years' experience we have developed and perfected a die head and control that is second to none.

All parts strong and substantial, yet so sensitive is the micrometer adjustment or set that bolts may be cut over or under size, and dies set to again cut exact size, at the will of the operator.

The adjustments made in a moment's time, and while the machine is running.

Column and headstock cast in one piece, assures perfect alignment and rigidity.

Our machines are standard with a great many large railroads and shipbuilding concerns on account of their simplicity, making them as accurate in the hands of an apprentice as in the hands of an experienced operator.

Made in single, double and triple sizes.

Dies can be changed from one size to another.

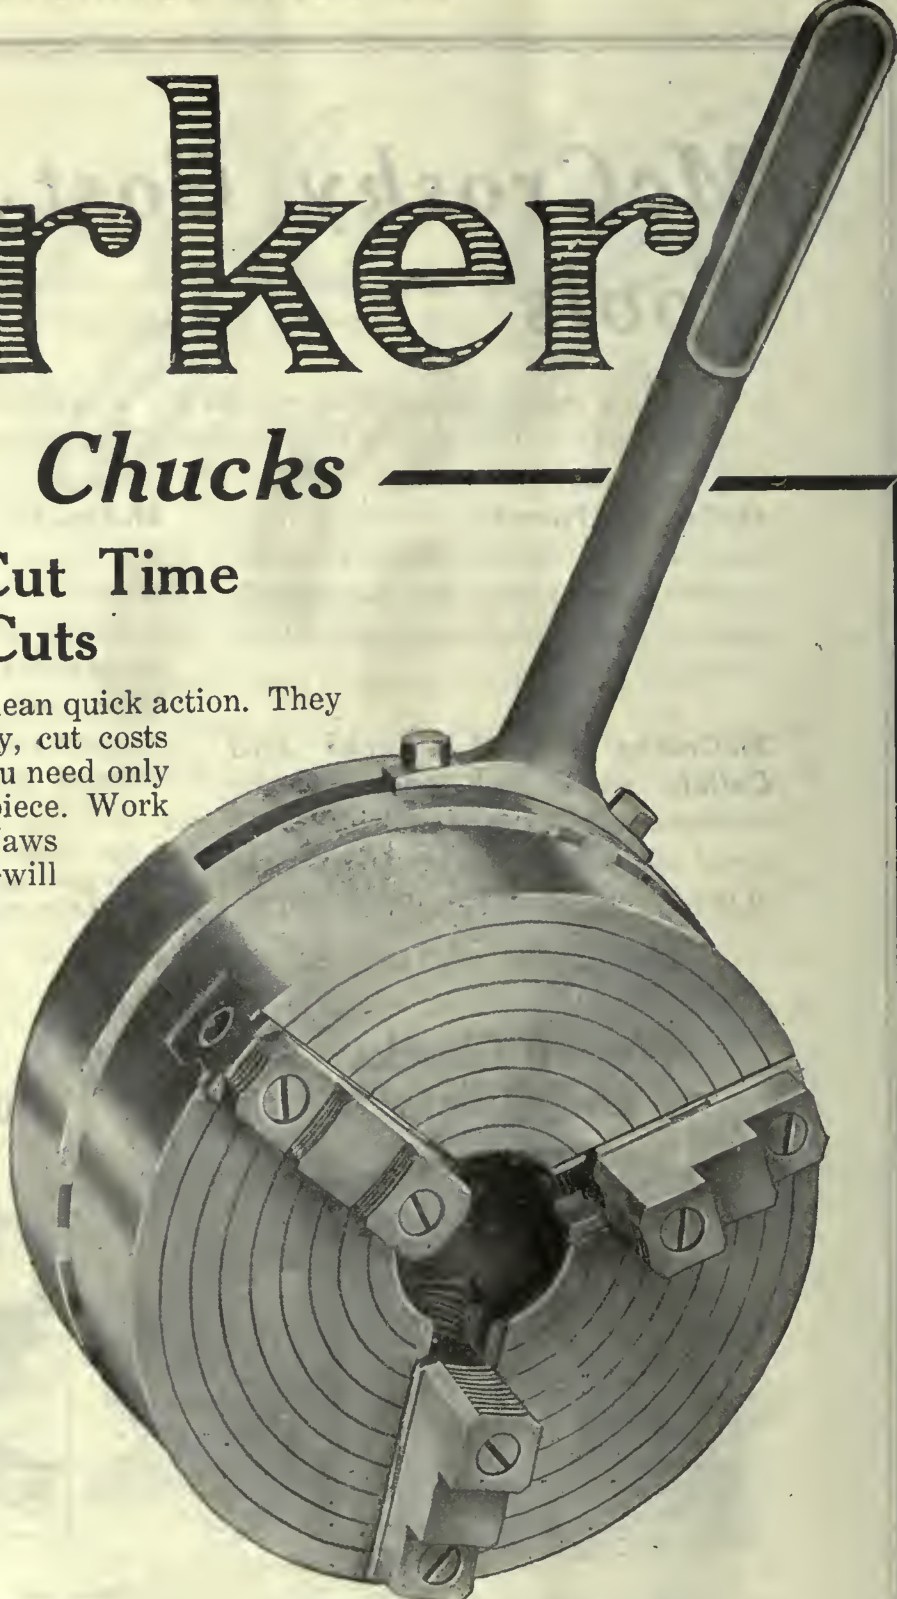
Barker

Wrenchless Chucks

Chucks That Cut Time Between Cuts



Barker Wrenchless Chucks mean quick action. They save hours of time each day, cut costs and increase production. You need only pull the lever and chuck the piece. Work is centered automatically. Jaws grip as tightly as the work will stand.

Jaws are ADJUSTED INDEPENDENTLY to any diameter, in the ordinary manner and for duplicate work, are OPERATED UNIVERSALLY AND SELF-CENTERING by the hand lever while the chuck is revolving or at rest.

The operating mechanism is combined with the chuck proper, forming a single unit. It takes no more time to mount than an ordinary chuck.

The planetary gear arrangement is so enclosed that no chips, dirt or grit can injure it—it is strong, sturdy and durable—not an experiment, but a tried and proven piece of mechanism.

Eliminates cost of installation of air compressor pipe system, valves, etc., and does the work more effectively. Overhang one-third less than any air chuck same capacity.

Barker Wrenchless Chucks are exceedingly valuable in every type of work done on turret, engine lathes or semi-automatic machines. It is worth money to you to investigate our chucks. Send for illustrated literature.

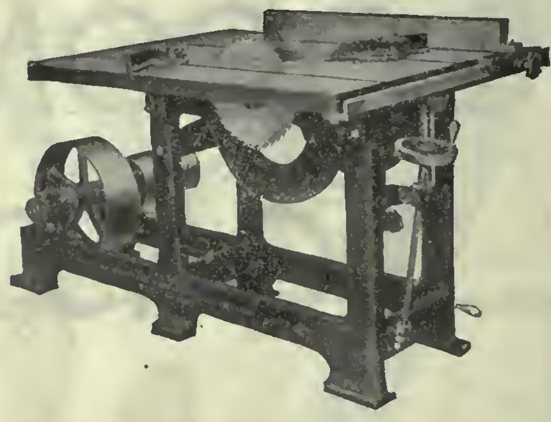
"Treat Your Machine as a Living Friend"

When you need a thing you pay for it whether you buy it or NOT.

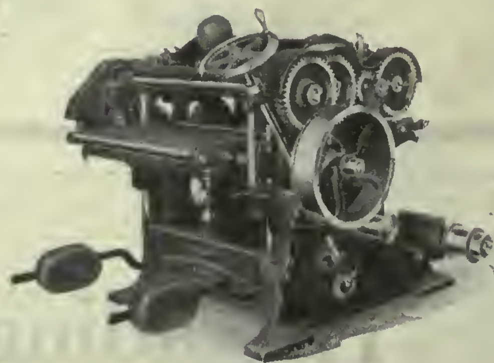
DO you need any Woodworking Machinery in your pattern shop or carpenter shop? A few suggestions are offered herewith.

Consult us if you want the best in Woodworking Machinery for making patterns, sashes, doors, furniture of all kinds, and any article manufactured from wood.



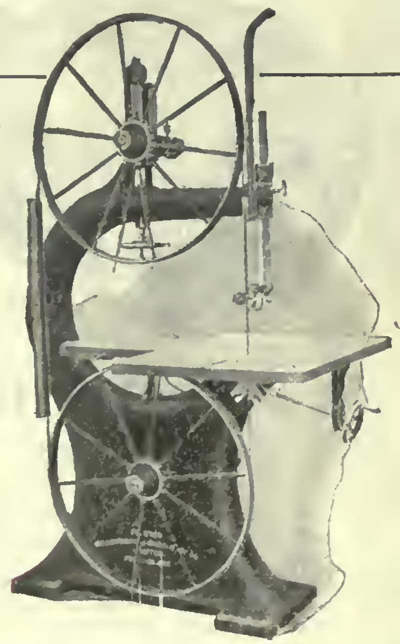
No. 125 Tilting Top Saw Table

A medium weight machine, very desirable for pattern shop work. Supplied with guard. Capacity up to 3" thick.



No. 143 Buzz Planer and Jointer

With ground safety cylinder and guard to conform with safety requirements of Government Inspectors.



No. 132-36" Band Saw with All-Steel Wheels

Guarded to meet requirements of Factory Inspector.

No. 121 Light Surface Planer

Planes either 20" or 24" wide x 8" thick. Much superior to a larger machine for running material within its limit.

The Preston Woodworking Machinery Co., Ltd., Preston, Ont.

If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.

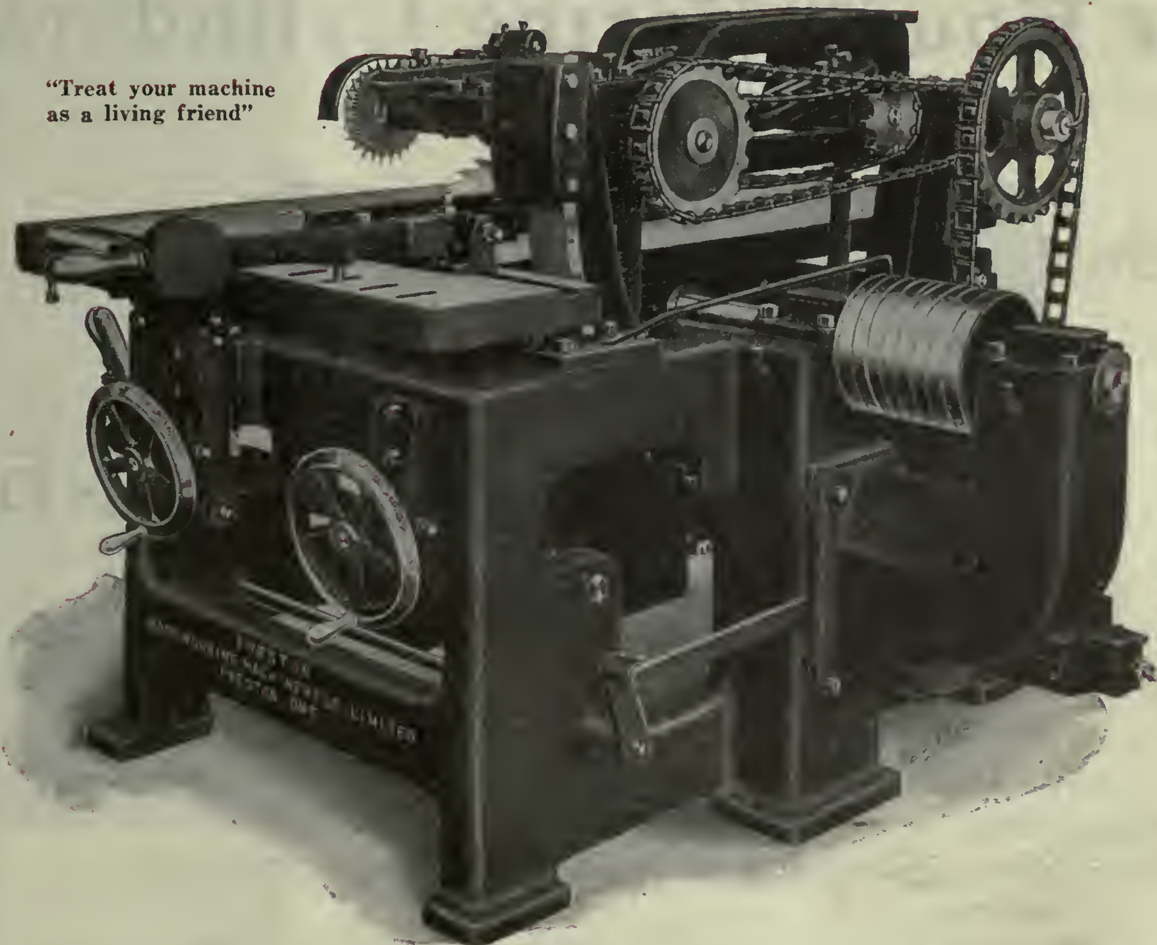
Get Ready for the Big Problem of Reconstruction

Look over your equipment and consider whether your efficiency might not be increased by the purchase of a

Preston No. 129 Power Feed Rip Saw

with Variable Feed

"Treat your machine as a living friend"



"Confidence is the mainspring of established trade. It is built up by selling customers the things they want and being sure they get what they think they're getting."

Predominant features:—The great saving in labor and the large increase in production possible.

The feed is variable from 0 to 240 ft. per minute and reversible if desired. The frame is one solid casting. Every bearing is self-oiling. Both table and upper works raised and lowered by hand wheels.

ADDRESS INQUIRIES TO THE MAYOR
PEMBROKE, ONT.

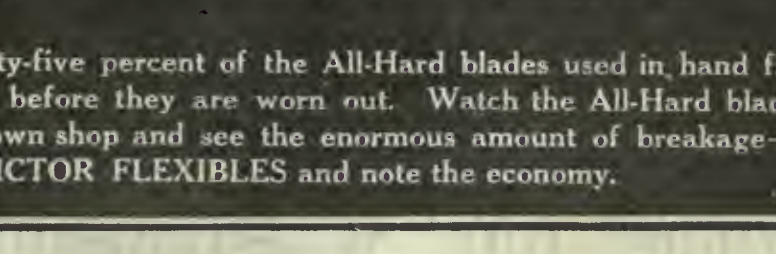
The high cost of tools should emphasize more than ever the importance of quality.

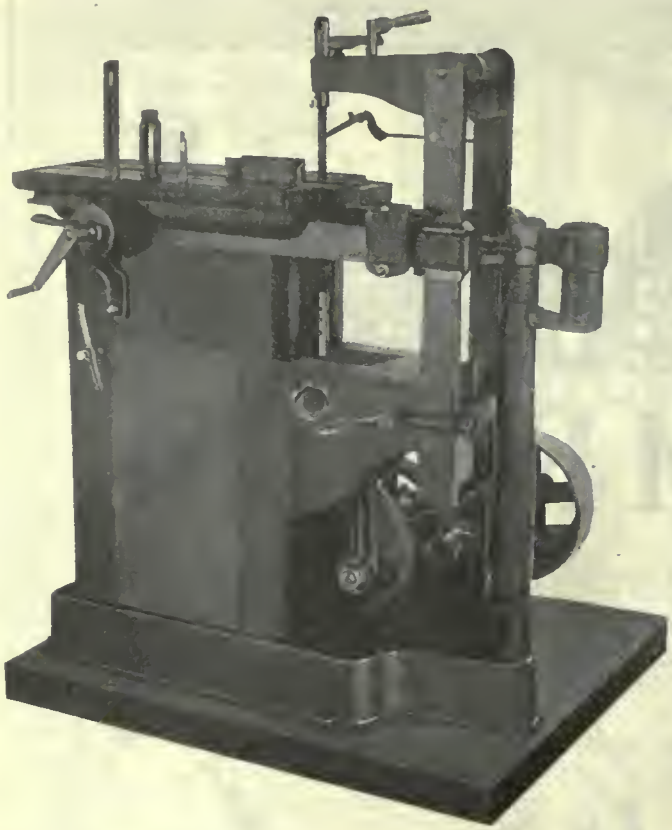
The high cost of hack saw blades ought to drive every hand blade user over to the saw that does not break in ordinary hand work.

VICTOR FLEXIBLE HACK SAW BLADES have exactly the same cutting power as the finest All-Hard on the market, and that they cannot be broken in use except by intentional abuse is an undisputable fact—which will represent a saving from twenty-five percent to thirty-three and one-third percent in breakage alone.

Seventy-five percent of the All-Hard blades used in hand frames break before they are worn out. Watch the All-Hard blades in your own shop and see the enormous amount of breakage—then use VICTOR FLEXIBLES and note the economy.

VICTOR SAW WORKS L'TD - HAMILTON, CANADA





A New Slotting Machine of the Milling Type

MANUFACTURED BY
RACINE TOOL AND MACHINE COMPANY
RACINE, WISCONSIN, U.S.A.

Manufacturers of
"Racine" High Speed Metal Cutting Machines

Of late years the machine-tool industry has been rather fixed in its character, and while from time to time improvements are made in the standard types, it is only at infrequent intervals that new types are produced or a familiar type adapted to a new line of work.

The Machine Tool we now introduce is different from the prevailing types and its possibilities embrace a wide field. It is yet without a suitable name to describe it, but is known as the No. 25 design. It can be simply described as an interior milling machine which operates a milling cutter having somewhat the character of a broach.

It is essentially a milling machine in the manner and character of its cut, but these milling operations are primarily intended to be performed on interior openings and for such surfaces as have heretofore only been possible to reach with slotting, broaching or keyseating machines. In its ability to execute these operations it fills a demand of thousands of machinists and shopmen who have always desired to mill interior surfaces and corners in order to obtain a fine and accurate surface.

The cutting member of the machine is practically identical with the teeth on the periphery of a standard milling cutter should these be laid out in a straight line. In their action they cut a chip similar to the chip produced by the milling cutter and the rate of cut and appearance of cut is essentially the same. However, there is this difference in the appearance of the cut, that because each tooth cuts the full length of the stroke on the cutting surface, it leaves no feed mark of the teeth on the actual surface where it is cutting, and the surface has a smooth, polished appearance.

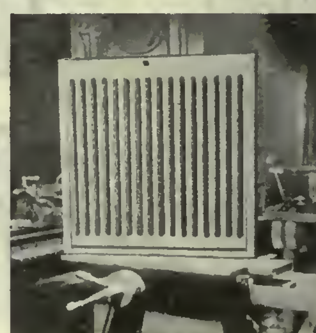
Machine can be arranged either belt or motor-driven, and will be equipped with a positive three-speed gear box drive of the tumbling gear type.

Photographs below show a few of many operations that can be performed on this machine.

Slots cut in offset tool posts.

Corundum stock molds and slotting bars.

Machined inside of openings in die blocks.



Slots cut in Tool Posts.

Wickes
Heavy Duty Engine Lathe

Double Back Geared Three-Step Cone. Double Plate Apron. Liberal size of parts, and high grade workmanship make the Wickes Lathe equal to the most severe service.

The Wickes has Special Ball Thrust Bearings; Steel Apron Gears, Coarse Pitch and Wide Face Gears, which are all well guarded. Let us tell you ALL about our lathes. Built for real service from 17" to 48" swing.

Wickes Radial Wall Drill

We can make prompt shipments. Made for rigid attachment to column or wall, or with bracket for vertical adjustment. Motor-driven. Operating lever has two points of leverage, one for light and one for heavy work, the one giving 10" and the other 5" movement to the spindle.

The arm is made of heavy channels, planed top and bottom and well supported and braced. The carriage has four turned rollers top and bottom, eight in all, a greater provision against tipping than can be found in any similar machine.

Spindles have bronze bearings and ball bearing thrust collars. Built in two sizes, with arm 8' to 18'. Write for full details to-day. We are in position to make prompt shipments.

"Keystone Quality" Will Still be There After Long Use Has Worn Away The Name

We like to think of that.

We like to think that the reputation of Keystone Tools is built upon a foundation of service with **Quality** the Keystone rather than a copyrighted name. For it is conceivable that imitators, or even the whims of courts, might rob us of our copyrighted name. But who could take "Keystone Quality" from Keystone Tools?

Write for name of nearest dealer.

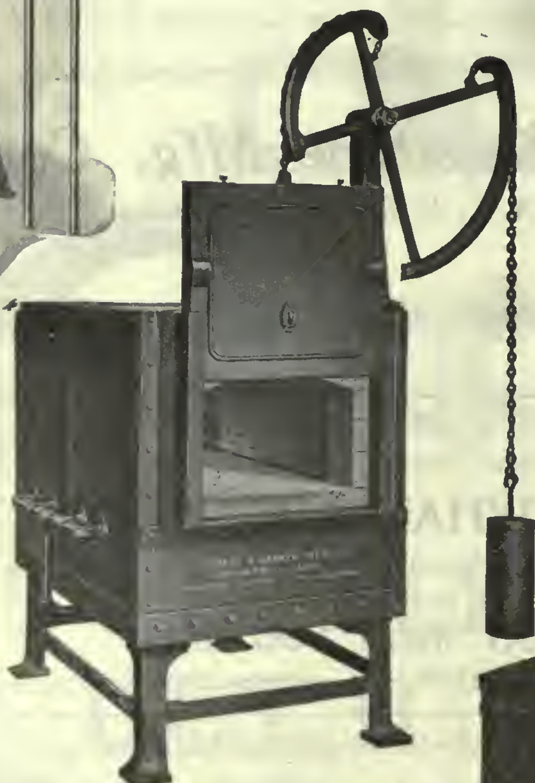
Gilbert & Barker Furnaces

For Immediate Deliveries

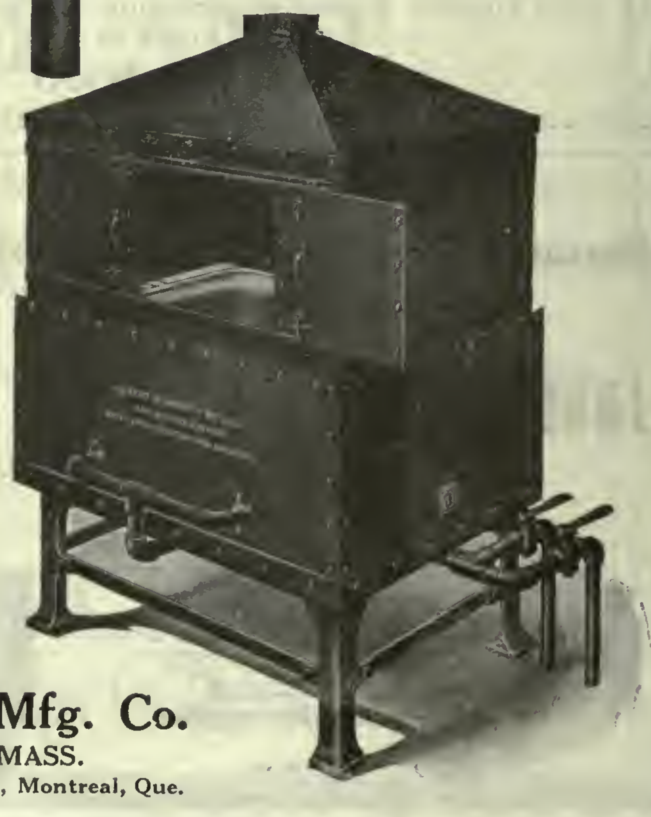


WHEN you require a heat treating furnace delivered to you promptly specify G. & B. in your order. Extensive manufacturing facilities enable us to keep ahead of the demand and you can secure certain standard types of furnaces for hardening and tempering directly from our stock.

G. & B. Furnaces Assure You 100% Efficiency In Heat Treating

The "C" type—especially designed for hardening taps, dies, milling cutters, etc., may be had in two sizes; one has a heating chamber 24 x 36 x 12 in. and the other 25 x 58 x 12 in.

The "K" type meets every requirement in the heat treating of high speed steels. Despite the fact that temperatures up to 2,600 deg. Fahr. may be obtained and maintained uniformly — this furnace rates very low on fuel consumption.



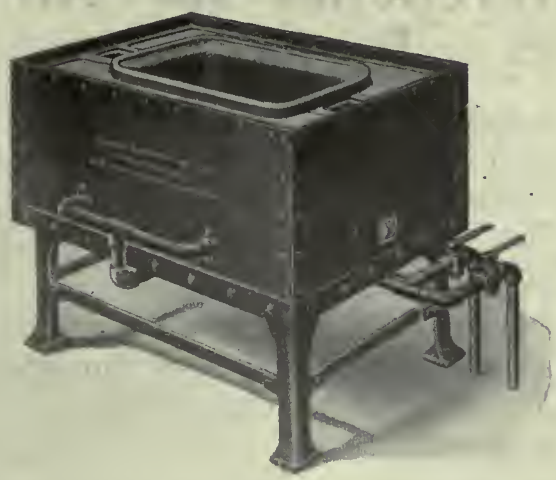
Enquiries Promptly Answered

Gilbert & Barker Mfg. Co.
WEST SPRINGFIELD, MASS.
Canadian Agents: Williams & Wilson, Montreal, Que.

Gilbert & Barker Furnaces

For All Heat Treating Purposes

THE G. & B. Furnaces you see illustrated here represent our smaller types which we are prepared to ship from stock on receipt of your order. There's a G. & B. Furnace for every heat-treating purpose. Standard designs cover all ordinary requirements and when you require a special furnace for special purposes we are prepared to suit your need precisely.



Advice on All Heat Treating Problems

For 50 years we have specialized in the manufacture of furnaces and our experience may be of service to you. We recommend the type of furnace that will fulfill your conditions most efficiently.

G. & B. Type "E" Furnaces have been recognized leaders in the heat treatment of steel in cyanide of potassium. Such fine work as dies with finely engraved working surfaces are handled with perfect ease in this furnace. It may be had in several usable sizes.

Then there is the Type "F" Lead Hardening Furnace adapted for work that cannot, because of its shape or size, be handled easily in a round pot. This type, as well as Type "E" may be supplied with or without a hood.

G. & B. Furnaces may be supplied for gas or oil fuel as desired—or if combination is desired we will fit with the G. & B. Combination Gas Oil Burner.

G. & B. Furnaces always produce just the correct heat, the oil or gas valve makes them extremely easy to operate—no ash to handle—no drafts to watch—just 100% efficient heat treating with the least amount of attention.

G. & B. Heat Treating Furnaces can save you money and it will pay you to get in touch with us.

Out in Three Minutes

The Walton in Operation

How long does it take you to extract a Broken Tap? More than three minutes? If it takes you longer valuable time is going to waste. What you require is the

WALTON TAP EXTRACTOR

Three minutes is average time this handy little device takes to back out a broken tap.

The WALTON is quick and simple. The strong, steel fingers slip into the flutes, grip the broken tap and away it comes.

If you have not got a Walton Tap Extractor handy you are causing yourself a lot of unnecessary trouble.

You can have a Walton Tap Extractor for 60 days' free trial. Anyway write for further information, it will pay you.

THE WALTON COMPANY

HARTFORD, CONN.

PUNCH PRESS WORK

What Can You Save?

By Using Parts Made in the Punch Press

Look over your standard parts, Mr. Manufacturer, and see what parts can be made (or could be made by slight change in design) by this process.

You will be surprised at the saving you can effect.

We make Blanking, Perforating, Drawing, Forming and all classes of dies and tools for plain or difficult stamping to suit the production required.

A Battery of presses is also available at our plant to manufacture parts for you with the understanding that you pay only for good parts made. Our facilities ensure prompt deliveries at right prices.

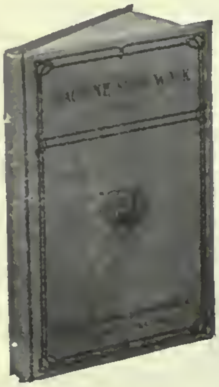
Mechanical Engineering Books

If you are desirous of improving yourself in your trade and so putting yourself in the position of making more money, these Mechanical Engineering Books will be found helpful.



MACHINE-SHOP WORK. By Frederick W. Turner, Instructor in Machine-Shop Work, Mechanics Arts High School, Boston. 208 pp., 241 illus. Cloth binding. The use of various hand tools is explained, followed by a comprehensive discussion of the lathe and lathe tools, with the methods of screw cutting, taper and eccentric turning, etc. The way to figure compound gears for screw cutting; drilling; boring; planers; shapers; slotters; milling machines and cutters; how to cut spirals, gears, cams, etc.; grinding; the operation of automatic machines. Price $1.50

MECHANICAL DRAWING. By Ervin Kenison, S.B., Assistant Professor of Mechanical Drawing, Massachusetts Institute of Technology. 176 pp., 120 illus. Cloth binding. Gives a course of practical instruction in the art of Mechanical Drawing, based on methods that have stood the test of years of experience. Includes orthographic, isometric and oblique projections, shade lines, intersections and developments, lettering, etc., with abundant exercises and plates. Price $1.00

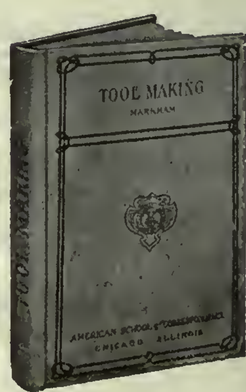
FOUNDRY WORK. Revised by Burton L. Gray, instructor in Foundry Practice, Worcester Polytechnic Institute. 224 pp., 191 illus. Cloth binding. A practical handbook on standard foundry practice, including hand and machine molding, cast iron, malleable iron, steel and brass casting, foundry management, etc. Includes use of various types of molding machines. Price, $1.00

PATTERN MAKING. By James Ritchey, Instructor in Wood Working, Armour Institute of Technology. 160 pp., 250 illus. Cloth binding. Shows the reader how to take the blueprint and from it make the pattern for any kind of casting under any condition. The allowances for shrinkage, draft, and finish are explained. Simple and built-up patterns of all kinds are clearly treated. Various special cases are taken up, such as pulleys, cranks, pipe connections, valves, etc. Price.......$1.50

MACHINE DESIGN. By Charles L. Griffin, S.B., Assistant Engineer, the Solvay-Process Co., American Society of Mechanical Engineers. 208 pp., 82 designs. Cloth binding. Explains in detail how to make the entire design of all kinds of machinery, how to lay out gears, etc., with complete specimen designs of numerous machines. Price ...$1.50

FORGING. By John Lord Bacon, Eng. and Supt. of Construction, with R. P. Shields & Son, San Diego, Cal., American Society Mechanical Engineers. Author of "Forge Practice." 128 pp., 180 illus. Cloth binding. A working handbook of practical instruction in hammering, working, forming, and tempering of wrought iron, machine steel, and tool steel, including the important modern development of electric welding. Price $1.00

TOOL MAKING. By Edward R. Markham, Consulting Mechanical Engineer, formerly Superintendent of the Waltham Watch Tool Co., American Society of Mechanical Engineers. Author of "The American Steel Worker." 224 pp., 325 illus. Cloth binding. Takes up the methods of treating tool steels—annealing, tempering, spring tempering, hardening, case-hardening, etc.; how to make drills and reamers of all kinds; the making of arbors and mandrels, taps, hobs, reamer and tap-holders, jigs, gauges, dies and die-holders of all kinds, counterbores, facing tools, milling cutters, hollow mills, and forming tools. Gives all necessary information for tool making in all its branches. Price $1.50



Sent postpaid on receipt of price. We can also furnish you with other standard works on Engineering in all its branches, including books for Civil Engineers, Contractors, Electricians, Foundrymen, Steam Engineers, Mechanical Engineers, Municipal Engineers, Railroad Engineers, Sanitary Engineers, Gas Engineers, Hydraulic Engineers, Technical Men.

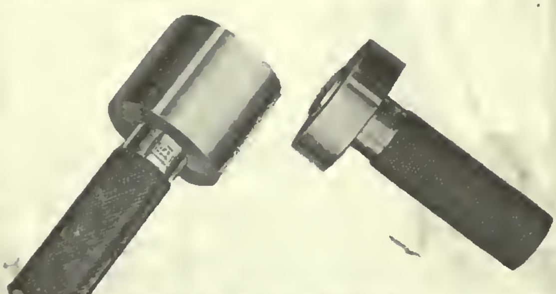
Martell Adjustable Hand Reamer

The most accurate and quickly adjusted hand reamer—one pair blades at right-hand angle and two pairs at left-hand angle to the center line—

Eliminates Chatter and Cuts

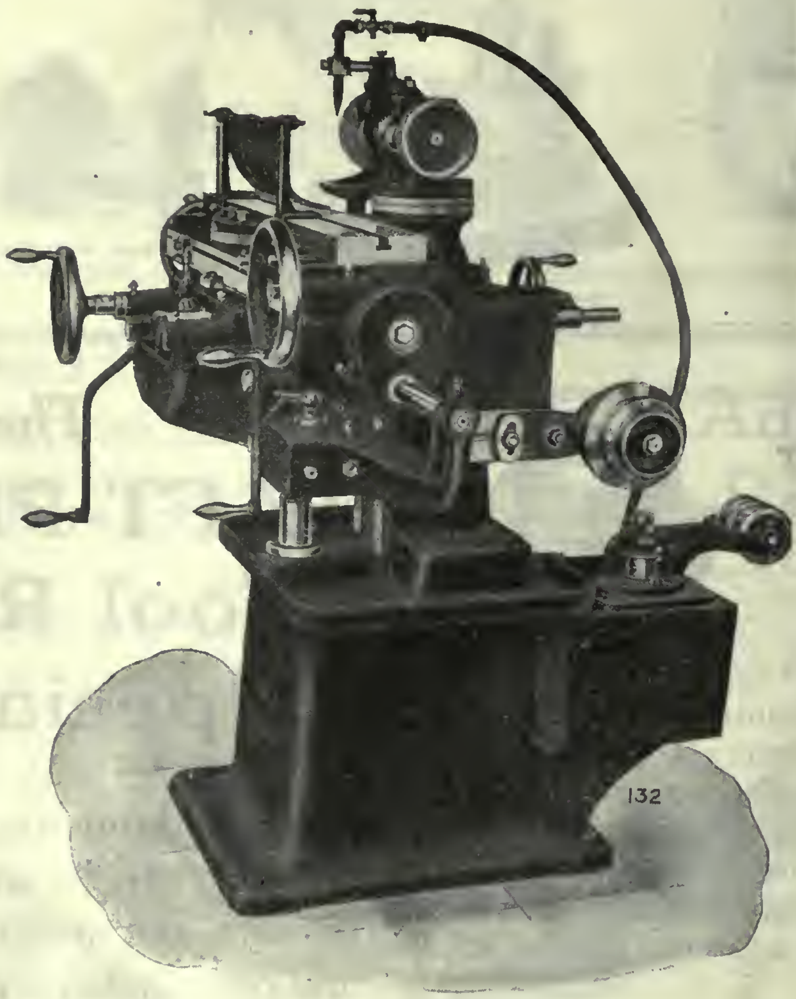
A More Nearly Perfect Round Hole

Cross-section of Adjustable Hand Reamer (Style 720). Note that three wedges are used under each blade instead of two. The reamer blade is finished so that it balances on the middle wedge and can only be seated on the end wedges by drawing up the clamping nut firmly. The blades are ground in this position so that when the pressure is released as when taking them out, they are actually concave instead of straight. By clamping the blades in this strained position they are held firmly throughout their entire length and the cutting edge held perfectly straight.



Individual Limit Plug Gauges.
Style 16-18

Limit Plug Gauges. Styles 11, 12 and handle 1.



No. 2 Oakley Universal and Tool Grinder

With Longitudinal Power Feed and Wet Grinding Attachment

Three Table Speeds	6"	per min.
	10½"	"
	18"	"

The stop dogs are hinged so that the operator may run the work past the setting to measure both external and internal work.

The machine can be operated by hand by disengaging the clutch.

Furnished with plain or universal equipment.

This machine is exceptionally

Heavy, Rigid and Accurate

Range—	
Longitudinal movement	17"
Vertical movement	10½"
Cross movement	9"
Work Centers—	
Maximum swing over table	10"
Maximum length	20"
Will swing a cutter at right angles	16"

This machine, within its range, will sharpen rapidly and accurately any style or shape of milling cutter, and when furnished as a universal machine, equipped with attachments for gear cutter, cylindrical internal and surface grinding, it will grind all work that comes to the tool room.

Bilton Gear Millers

You can have a machine in your factory that is a manufacturing and producing unit—a machine that has a wide range of usefulness and adaptability—a machine that can be operated in conjunction with other machines at very little additional cost. Such is the record in many plants for

BILTON GEAR MILLERS

Made in three sizes (4"-6"-8" dia.) for cutting spur and bevel gears, ratchets and many difficult milling operations.

	Dia.		Stroke
No. 1 GEAR MILLER..............	4"	18 P.	2"
No. 1½ GEAR MILLER..........	4"	16 P.	2"
No. 2 GEAR MILLER..............	6"	14 P.	3½"
No. 2½ GEAR MILLER..........	6"	10 P.	3½"
No. 3½ GEAR MILLER..........	8"	8 P.	5½"

The moderate cost of these machines makes them a desirable investment. Since they can be used for varied classes of work, the first cost can be realized within a comparatively short period.

The special features found only on Bilton Gear Millers make them very desirable for high production and encourage the use of these machines for many different parts, or operations. These characteristics are:—

Full automatic action; positive and direct indexing to the work; cutter clears work while indexing takes place; quick releasing fixtures for removing work; high production through quick action of machine; automatic stop of feed when work is done; easily controlled; operator can run other machines.

Some users of "BILTON" Gear Millers:

Singer Mfg. Co., Elizabethport, N.J.; Remington Typewriter Co., Ilion, N.Y.; Underwood Typewriter Co., Hartford, Conn.; Jackson-Church-Wilcox Co., Saginaw, Mich.: Gisholt Machine Co., Madison, Wisconsin; Scott & Williams, Inc., Laconia, N.H.; and 500 other good concerns.

We would appreciate the opportunity to show how "Bilton" Gear Millers can be adapted to your work. Send us samples or drawings of your work, and we will tell you how efficiently it can be done. No obligation on your part. Ask for copy of Catalog No. 30.

Foreign Agents—Chas. Churchill & Co., Ltd.; Alfred Herbert, Ltd.

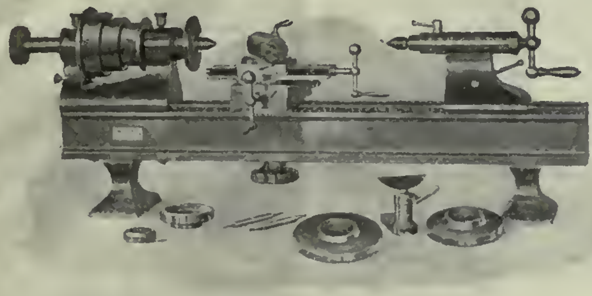
INDEX TO ADVERTISERS

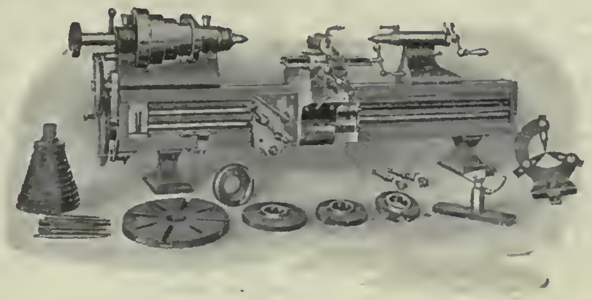
Continued from page 442

Plain Precision Bench Lathes—Back Geared Precision Lathes—Precision Turret Lathes



No. 504. Plain Precision Lathe

8" swing. 18" between centers. Wire chuck capacity, ⅝" dia. This lathe is designed for simple but accurate tool room and manufacturing work, and it may be equipped with attachments for a large variety of operations, such as screw cutting, milling, grinding, etc. The lathe is finely finished all over.

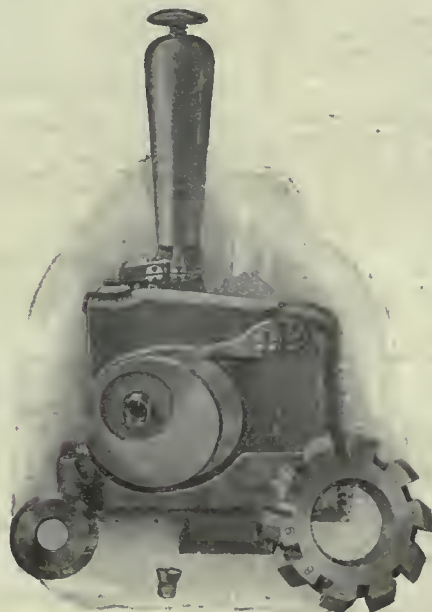


No. 505. Plain Precision Bench Lathe

8" swing. 18" between centers. Wire chuck capacity, ⅞" dia. This lathe is of heavier construction than the No. 504, and is suitable for light manufacturing work where accuracy and speed are essential. It was designed primarily for plain turning and allied work; consequently, attachments which may be supplied are limited. It is finished only on bearing surfaces—other surfaces being well painted.

No. 608. Back Geared Precision Lathe

8½" swing. 20" between centers. Wire chuck capacity, ⅝" dia. This lathe is designed for most accurate tool room, experimental and model room and manufacturing work. It may be equipped with a multitude of attachments for a wide range of work. This lathe, as well as the other bench lathes, may be mounted on combination oil pan and stand, or oak cabinet, and may be either belt or direct motor driven.



Illustrating Method of Mounting Cutting Tool

The Improved Tool facilitates Cutter indexing, provides minimum operating-lever travel with positive lock and makes possible finer adjustment of the cutting-tool. All moving parts are adjustable for wear, cutters are quickly and rigidly mounted with extreme accuracy and the tool may be quickly mounted on the lathe.

RIVETT LATHES

are Accurate

Illustration on left shows No. 705. Precision Hand Turret Lathe

8" swing. Maximum distance between chuck face and turret face, 17¾". Travel of turret slide, 4". Wire chuck capacity, ⅞" dia. This machine is designed for turret work where the production does not warrant the purchase of a full automatic turret lathe. It is easily set up for a large variety of work and can be operated with great rapidity.
